GAM run 06-15

by Richard Smith, P.G.

Texas Water Development Board Groundwater Availability Modeling Section (512) 936-0877 September 1, 2006

REQUESTOR:

Mr. Allan Lange, General Manager for the Lipan-Kickapoo Water Conservation District.

DESCRIPTION OF REQUEST:

Mr. Lange requested the following information for his district from the groundwater availability model (GAM) for the Lipan Aquifer for his management plan:

- 1) estimated annual amount of recharge from precipitation to the district;
- 2) estimated annual volume of water that discharges from the aquifer to springs and any surface water body including lakes, streams, and rivers;
- 3) estimated annual volume of flow into and out of the district within each aquifer and between each aquifer in the district; and
- 4) estimated annual amount of groundwater being used in the district on an annual basis.

METHODS:

To address the request, we ran the Lipan Aquifer GAM for 1980 to 1998 and averaged the results for each layer in the model to obtain values.

PARAMETERS AND ASSUMPTIONS:

The Lipan Aquifer GAM has a root mean square of the errors of 40 feet. In the Lipan Aquifer model, each model cell is ½ mile by ½ mile with a resulting cell area of ¼ square mile or 160 acres. The model is one layer which is 400 feet thick. Pumpage for the model is based on a yearly time step and is from the centroid of each ¼ square mile grid cell. The springs, lakes, and rivers included in the model are shown in Figure 1.0.

We used the following assumptions in this analysis:

- see Beach and others (2004) for assumptions and limitations of the GAM;
- recharge represents long-term average climatic conditions for 1980 through 1998;

RESULTS:

Recharge and water budget

A groundwater budget summarizes how the model estimates water entering and leaving the aquifer. The groundwater budget for the average values from the transient model (1980 to 1998) is shown in Table 1. The components of the budgets shown in Table 1 include:

- Precipitation recharge—This is the areally distributed recharge due to precipitation falling on the outcrop areas of the aquifers within the district.
- Surface water inflow and outflow—This is the total surface water entering the aquifer (inflow) through streams or reservoirs, or total surface water exiting the aquifer (outflow) to streams, reservoirs, drains, or through evapotranspiration.
- Net inter-aquifer flow—This describes the vertical flow, or leakage, between two aquifers. This flow is controlled by the relative water levels in each aquifer and aquifer properties of each aquifer. "Inflow" to an aquifer from an overlying or underlying aquifer will always equal the "Outflow" from the other aquifer. In the case of the Lipan, the aquifer is modeled as a single layer and is underlain by a no-flow boundary.
- Lateral flow into and out of district—This component describes lateral flow within the aquifer between the district and adjacent counties.

Table 2 shows the pumpage, in acre-feet per year, used in the GAM for cells overlain by the Lipan-Kickapoo Water Conservation District.
