Open-File Report 99-02

Updated Evaluation of Water Resources in Part of North-Central Texas

By

Lon Langley

September 1999

ABSTRACT

This updated evaluation of water resources of part of north-central Texas includes all or portions of Collin, Cooke, Dallas, Delta, Denton, Ellis, Fannin, Grayson, Hood, Hunt, Johnson, Kaufman, Lamar, Montague, Navarro, Parker, Red River, Rockwall, Tarrant, and Wise Counties. This report is in response to Senate Bill 1, passed in 1997 by the 75th Texas Legislature. This Act calls for the identification of areas in the state experiencing or expected to experience critical groundwater problems within the next 25-year period.

A reduction in groundwater withdrawals since 1990 has slowed water-level declines in some parts of the study area. Water levels in the Trinity aquifer have remained stable since 1989 with the exception of Wise, Tarrant, and Johnson Counties. Water-level declines of about 100 feet have occurred in southwestern Wise County. The Dallas-Fort Worth metroplex area in northeastern Tarrant County has experienced water-level declines of 200 feet. Minor water-level declines of approximately 50 feet have occurred in southern Johnson County. The northern parts of Johnson County, as well as southern Denton and Tarrant Counties, have experienced a rise in water levels from 50 to 200 feet. Water levels have not changed significantly in the Paluxy aquifer. Southern Wise County and Denton County have undergone minor water-level declines of 5 to 30 feet. Water levels in the Woodbine aquifer have remained stable with the exception of northern Collin County, the central to northeastern portion of Denton County, and northern Grayson County where declines of 10 to 60 feet have been observed.

Overall, groundwater quality has not degraded appreciably since the last reporting period in 1990. Average TDS values for the Trinity aquifer were 718 mg/l. The Paluxy aquifer had average TDS values of 607 mg/l. The Woodbine aquifer had the highest TDS values, averaging 877 mg/l. This is primarily due to high sulfate levels associated with extensive lignite beds.

Groundwater use is projected to decline in the study area, which would allow for conservation of groundwater reserves. Continual conversion to surface water use within the study area should allow future demands to be met. These projections suggest that adequate supplies of usable surface and groundwater exist to meet current and future needs of the study area through the year 2030.

INTRODUCTION

North-central Texas is the most populous region in the State, containing 24 percent of the population and is expected to more than double by 2050 (TWDB, 1997). The area accounts for approximately 6 percent of the State's annual water use. By 2050, water use in this area is expected to increase about 90 percent (TWDB,1997). Water is important to sustain the area's growing population and an economy. Although there has not been any major water deficits in the area, groundwater levels have declined 100 to 1,100 feet in the Trinity aquifer and 200 to 400 feet in the Woodbine aquifer since 1900 (Mace and others, 1994).

This report is an update to Texas Water Development Board (TWDB) Report 318, *Evaluation of Water Resources in Part of North-Central Texas*, by Baker and others, published in January 1990. TWDB Report 318 was prepared in response to the 1985 passage of House Bill 2 by the 69th Texas Legislature. This Act, in part, focused on addressing areas of the State where groundwater quality and quantity were deteriorating. This report is in response to Senate Bill 1 (SB-1), passed in 1997 by the 75th Texas Legislature. This Act requires identification of those areas of the State that are experiencing or are expected to experience critical water problems within the immediately following 25-year period. This may include shortages of surface water or groundwater, land subsidence resulting from groundwater withdrawal, and contamination of groundwater supplies. Presently, no groundwater districts have been created in the study area.

This report updates the hydrogeological conditions, water demands, and water availability in the study area. Water levels and water quality were used to assess the current status of the groundwater resource and possible future trends. Population, historical water use, and projected water demands were compiled from TWDB reports and databases and analyzed for the study area.

The study area is in north-central Texas (Figure 1) and is defined by the Red River to the north, the outcrop edge of the Trinity aquifer to the west, the downdip limit of the Woodbine aquifer to the east (as defined by the slightly saline line), and the southern boundaries of Hood, Johnson, and Ellis Counties to the south. The study area lies within the Red, Sulphur, Sabine, Trinity, and Brazos River basins. It encompasses all or parts of Collin, Cooke, Dallas, Delta, Denton, Ellis, Fannin, Grayson, Hood, Hunt, Johnson, Kaufman, Lamar, Montague, Navarro, Parker, Red River, Rockwall, Tarrant, and Wise Counties.

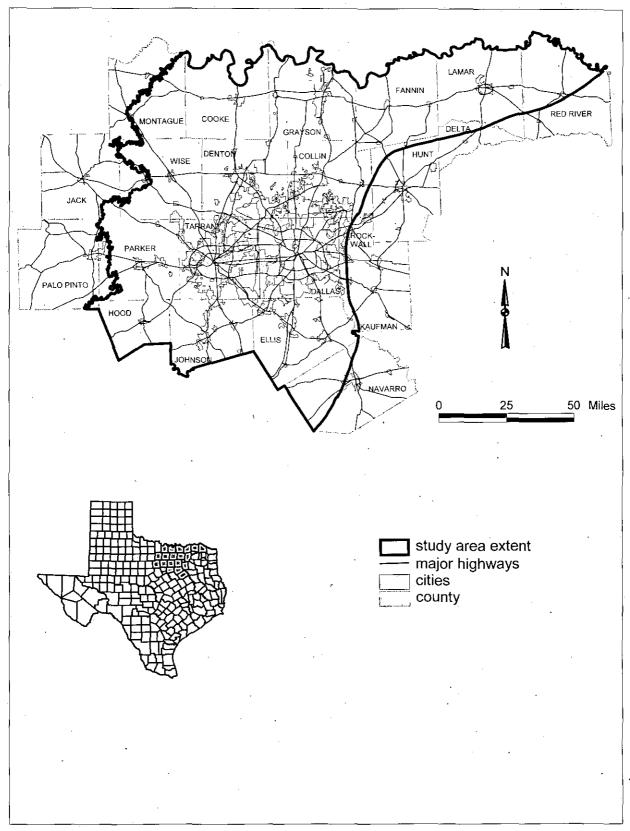

Figure 1. Location of the study area in north-central Texas.

HYDROGEOLOGY

Groundwater flow and the groundwater resource is controlled, in part, by the geology in the region, water levels, precipitation as it relates to recharge, and water quality.

Geology

The primary aquifers in the area include the Trinity and Woodbine aquifers with minor amounts of water also produced from the Blossom and Nacatoch Sands. These aquifers are briefly discussed below. The geology and hydrogeology of the study area are discussed in more detail by Muller and Price (1979), Nordstrom (1982), and Baker and others (1990).

The Trinity aquifer is composed of Cretaceous age formations of the Trinity Group and extends through the central part of Texas from the Red River to the north and through the Hill Country to the south (Ashworth and Hopkins, 1995). The Trinity aquifer is the only major aquifer within the study area (Figure 2) and includes the Antlers, Twin Mountains, and Paluxy Formations. The Antlers Formation consists of the Twin Mountains and Paluxy Formations where the Glen Rose Formation confining layer pinches out. Because the Antlers and Twin Mountains Formations are closely related hydrologically, they are often discussed together (e.g. Baker and others, 1990).

Outcrops of the Antlers Formation are located mainly in Montague, Wise, and Cooke Counties. The Antlers Formation is about 400 feet in thickness near the outcrop and increases to about 900 feet in southeast Grayson County. The Twin Mountains Formation outcrops in the western part of the study area in Hood, Parker, and Wise Counties. The thickness of the Twin Mountains Formation varies from less than 200 feet near the outcrop to approximately 1,000 feet at the downdip limit of fresh to slightly saline water. The Paluxy Formation outcrops in Hood, Parker, Tarrant, and Wise Counties. The thickness of the Paluxy Formation varies considerably, from about 400 feet in the northern part of the study area to less than 100 feet in the southern part (Nordstrom, 1982).

Minor aquifers in the area consist of the Woodbine Formation, the Blossom Sand and the Nacatoch Sand (Figure 3). The Woodbine Formation outcrops in Johnson, Tarrant, Denton, Cooke, and Grayson Counties (Baker and others, 1990). The Woodbine Formation trends in a north-south direction extending from the Red River to the north and to northern McClennan County to the south. The thickness of the Woodbine Formation ranges from about 230 feet near the southern extent of the outcrop to approximately 700 feet near the downdip limit of fresh to slightly saline water.

The Blossom Sand outcrops in central Fannin, Lamar, and Red River Counties. The Nacatoch Sand is exposed in Delta, Hunt, Kaufman, Lamar, Navarro, and Red River

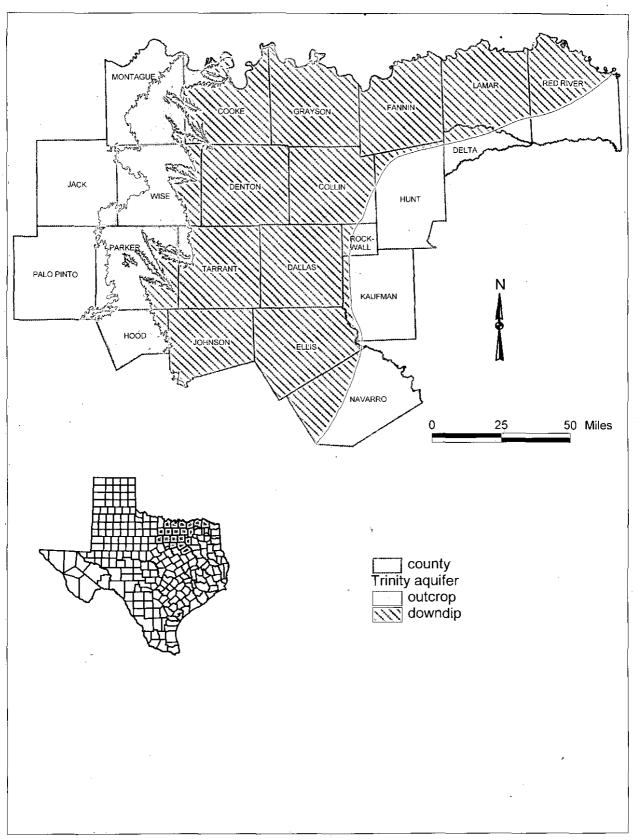

Figure 2. Location of the Trinity aquifer in the study area.

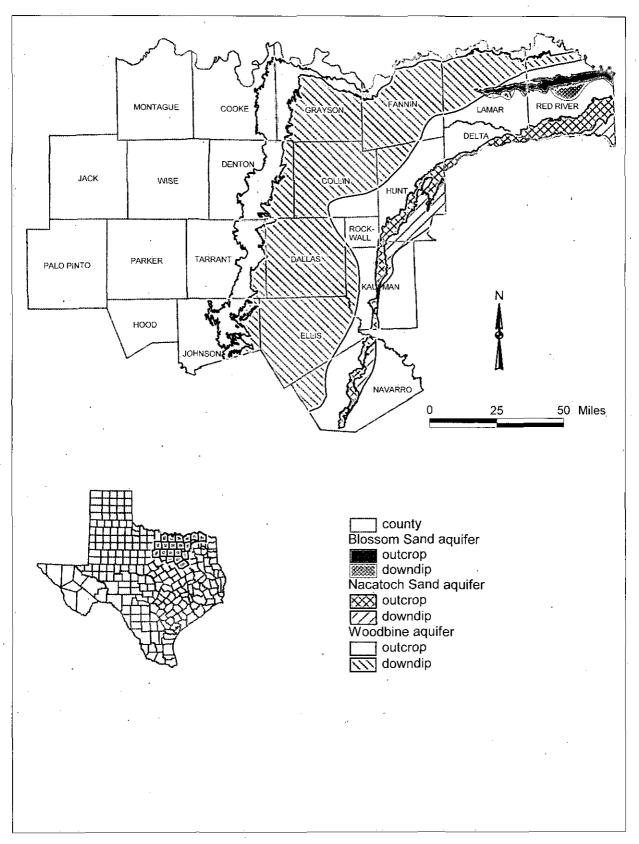

Figure 3. Location of minor aquifers in the study area.

Counties (Baker and others, 1990). Because wells from these aquifers typically produce small yields of usable water (Baker and others, 1990), they will not be discussed in this report. The Blossom and Nacatoch Sands are discussed in more detail by Muller and Price (1979), Nordstrom (1982), Ashworth (1988), and McLaurin (1988).

Water-Level Fluctuations

Water-level changes from 1989 to the present are shown in contour maps, hydrographs, and tables constructed using groundwater-level elevation data from the TWDB groundwater database for the Antlers and Twin Mountains Formations, the Paluxy Formation, and the Woodbine Formation (TWDB, 1998a; control data in Appendix A). Most of the wells used to investigate water levels in TWDB Report 318 (Baker and others, 1990) are also used in this report. Wells 19-23-701, 32-37-702, and 33-19-301 were not used due to unreliable water-level measurements owing to well problems and were replaced with nearby wells 19-15-701, 19-60-601, and 33-50-502, respectively.

Groundwater flow in the Antlers and Twin Mountains Formations of the Trinity aquifer is generally to the east-southeast (Figure 4). A cone of depression caused by heavy pumpage is centered in northern-eastern Tarrant County and extends into Dallas and Denton Counties (Figure 4). Another potential cone of depression may exist in northwest Ellis County. The largest change in water level between 1989 and 1997 is centered around the city of Euless within the Dallas-Ft. Worth metroplex (Figure 5). Water-level declines in this area range from 50 to 200 feet and extend from northeastern Tarrant County to western Dallas County. Water levels have risen approximately 100 feet in southern Denton County and 200 feet in southeastern Tarrant County and southwestern Dallas County. Water levels have recovered in northern Johnson County but continue to decline in the southern part of the county.

Water levels in individual wells in the Antlers and Twin Mountains Formations show a variety of historical water-level changes (Figure 6). Some wells show little change over the past 30 years (19-20-801, 19-51-901, 19-15-701) while others show overall declines ranging from 200 to 500 ft (32-46-907, 19-24-702, 32-16-101). A well in Dallas County (33-19-101) shows a water-level decline of 143 feet from 1970 to 1985 and has recovered 99 feet since 1985. Since 1989, water levels in selected wells have declined as much as 235 feet and rebounded as much as about 75 feet (Table 1). Rates of water-level changes between 1989-1997 range from +8.33 to -29.36 feet per year (Table 1).

Groundwater flow in the Paluxy Formation is generally to the east-southeast (Figure 7). Water levels have declined in the northern portion of the aquifer and risen for most of the southern portion since 1989 (Figure 8). The greatest water-level differences between 1989 to 1997 occur north of Parker and Tarrant Counties. Water-level elevations in Denton County have decreased 15 to 35 feet, while most of Tarrant County shows an increase of 5 to 25 feet (Figure 8).

Table 1. Water-level differences within the Antlers and Twin Mountains Formations, Trinity aquifer (based on data from TWDB, 1998a).

Water levels in individual wells in the Paluxy Formation show a variety of historical water-level changes (Figure 9). Two wells show little change over the past 30 years (19-60-601, 32-02-101) while one shows an overall decline of about 220 ft (18-49-101). A well in Tarrant County (32-16-201) shows large historical variations including a 220 foot rise between 1972 and 1976 and 25 to 100 ft variations since 1980. Since 1989, water levels in selected wells have declined as much as 55 feet and rebounded less than 3 feet (Table 2). Rates of water-level changes between 1989-1997 range from +0.36 to -13.75 feet per year (Table 2).

<u>+</u>

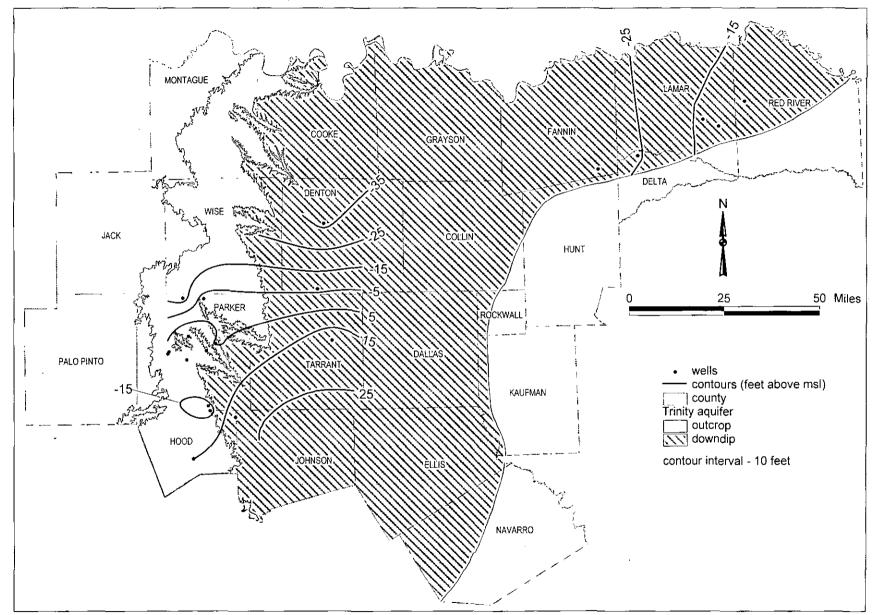

Figure 8. Approximate water-level differences in the Paluxy Formation, Trinity aquifer, between 1989 and 1997.

12

.

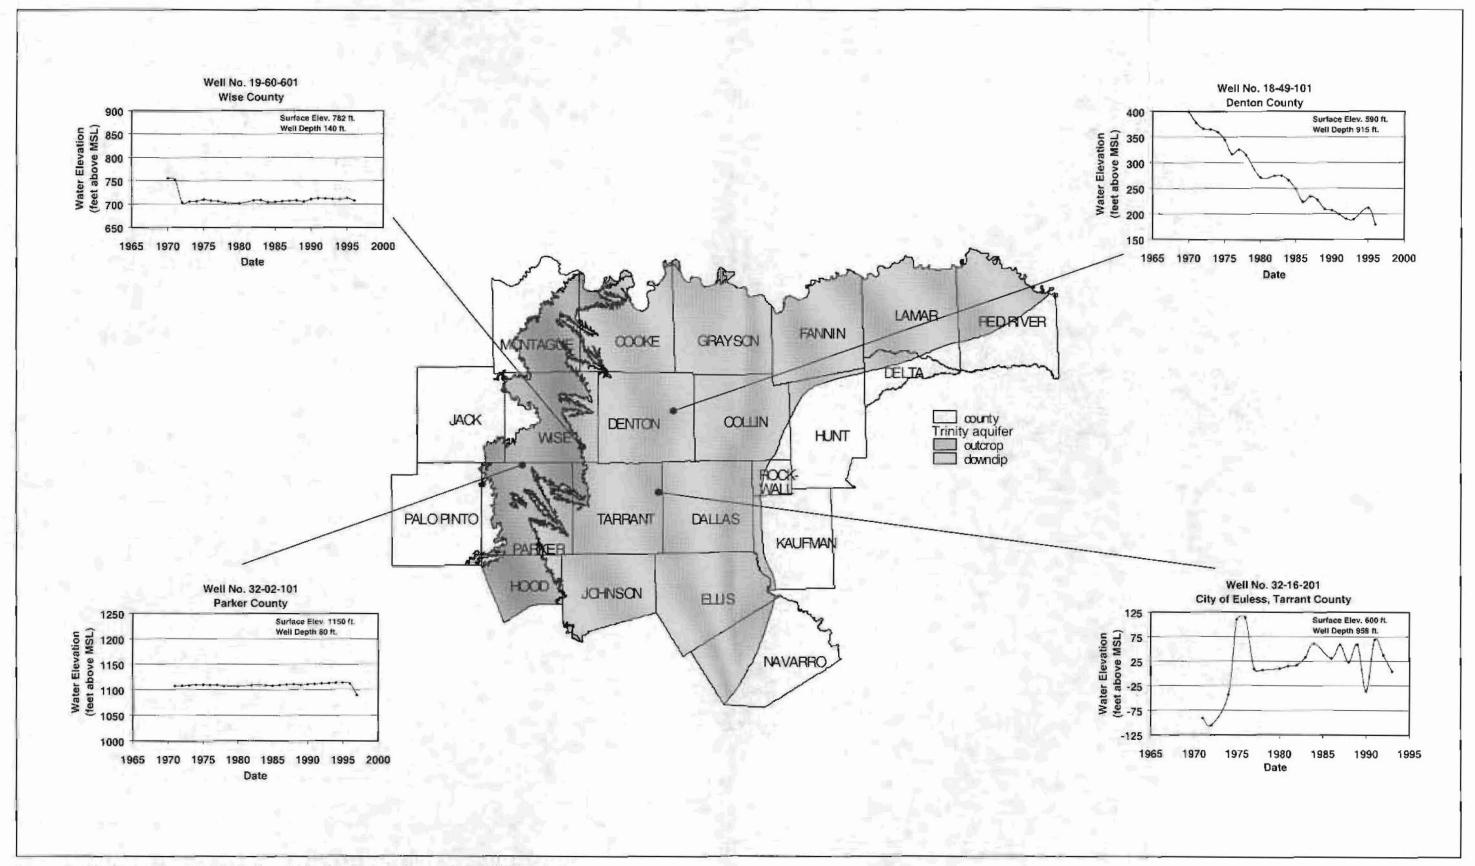

Figure 9. Hydrographs of selected wells in the Paluxy Formation, Trinity aquifer.

Groundwater flow in the Woodbine aquifer is generally to the east-southeast (Figure 10). Water-level elevations have not changed significantly since 1989 (Figure 11). The greatest water-level differences occur in northern Collin County, the central to northeastern portion of Denton County, eastern Cooke County, and northern Grayson County (Figure 11). Water levels have declined an average of 10 feet over most of this area, with declines of 60 feet observed in the northern part of Grayson County. Water levels in Johnson County have remained steady from 1989 to 1997.

Water levels in individual wells in the Woodbine aquifer show a variety of historical water-level changes (Figure 12). Some wells show little change over the past 30 years (18-25-301, 32-39-505, 17-12-101) while others show overall declines (18-50-202, 18-38-302, 33-50-502). A well in Fannin County (18-38-302) shows a decline of about 179 feet from 1971 to 1989 with generally stable water levels since 1989. Since 1989, water levels in selected wells have declined as much as 42 feet and rebounded less than 3 feet (Table 3). Rates of water-level changes between 1989-1997 range from +0.34 to -5.94 feet per year (Table 3).

			1989-1996	-5.94	-41.60

Table 3. Water-level differences within the Woodbine aquifer (based on data from TWDB, 1998a).

Precipitation

The primary source of recharge to the Trinity and Woodbine aquifers is infiltration from precipitation falling on the outcrop (Nordstrom, 1982). The amount of recharge to the Trinity and Woodbine aquifers is estimated to be less than one inch per year (Nordstrom, 1982). This amounts to about 3 percent of average annual precipitation in the area.

Annual precipitation varies from 28-32 inches in the western part of the study area to 44-48 inches in the eastern part (Nordstrom, 1982). From 1960 through 1996, average

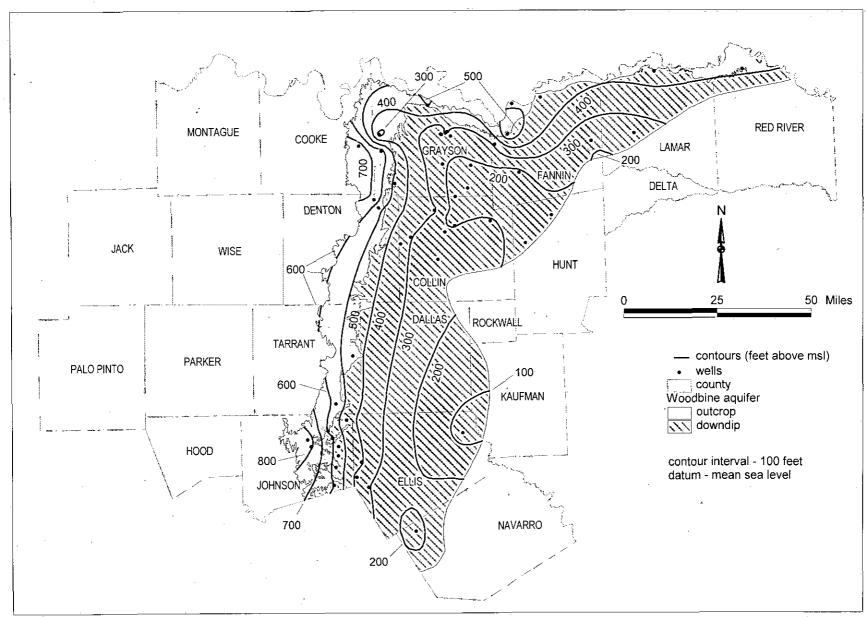

Figure 10. Approximate water-level elevations in the Woodbine aquifer, winter 1997.

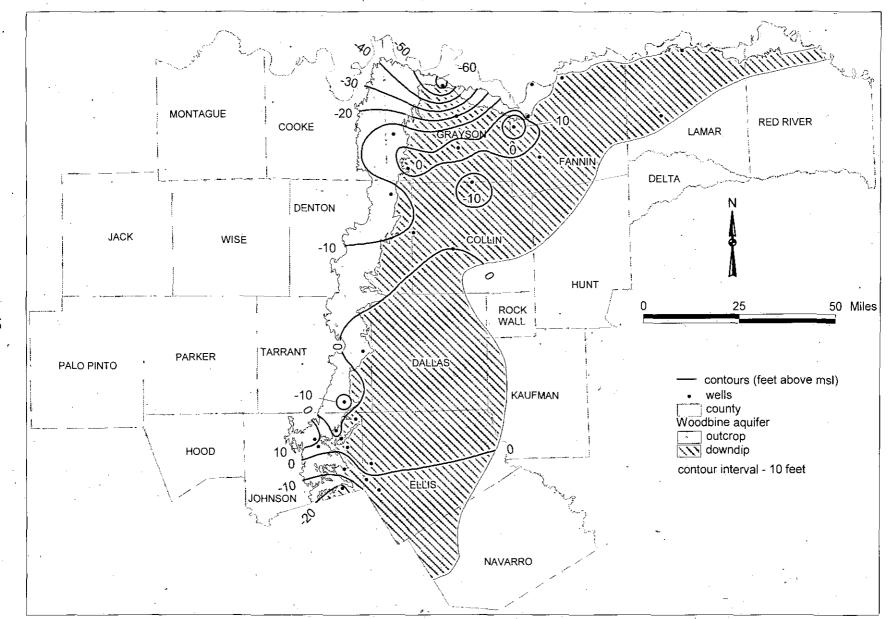

Figure 11. Approximate water-level differences in the Woodbine aquifer, between 1989 and 1997.

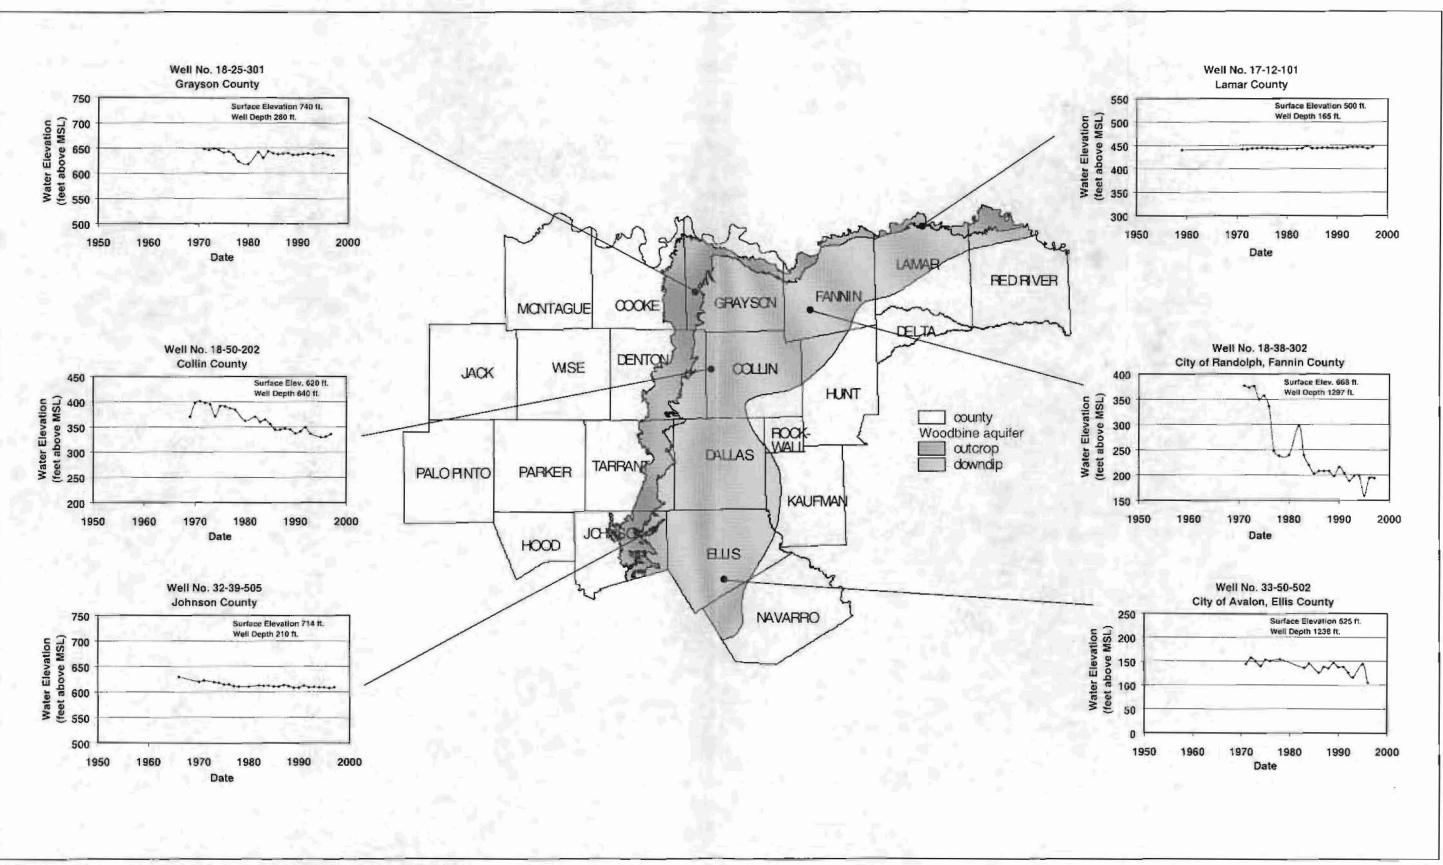

Figure 12. Hydrographs of selected wells in the Woodbine aquifer.

annual precipitation at the Weatherford gage, located on the Trinity outcrop, has been 33 inches with a minimum of 19 inches in 1963 and a maximum of 49 inches in 1991 (Figure 13). Precipitation has been above average from 1989 through 1996.

From 1965 through 1996, average annual precipitation at the Denton SE gage, located on the Woodbine outcrop, has been 38 inches with a minimum of 27.5 inches in 1972 and a maximum of 57 inches in 1981 (Figure 14). Precipitation has been above average from 1992 through 1995.

Water Quality

The TWDB collected water samples following standard procedures (Nordstrom and Beynon, 1991) from the Trinity and Woodbine aquifers between 1990 to 1998 throughout the study area. Samples were analyzed for major anions and cations and selected trace elements including nitrate, nitrogen (as NO₃), sulfate, chloride, sodium, calcium, magnesium, silica, total potassium, strontium, carbonate, bicarbonate, and fluoride.

Measured concentrations were compared to the primary constituent levels. Primary constituent levels are the maximum contaminant levels for a pollutant that is allowed in drinking water which will cause no adverse effects on human health. Secondary constituent levels are usually based on reasons such as color, taste, odor, staining, and scaling and are recommended limits (30 TAC §290, 1999).

Maximum contaminant levels (MCLs) for applicable constituents (30 TAC §290, 1999) include:

- a secondary constituent level of 1,000 mg/l for TDS,
- a primary constituent level of 10 mg/l for nitrate as nitrogen,
- a primary constituent level of 44.3 mg/l for nitrate as nitrate,
- a secondary constituent level of 300 mg/l for sulfate,
- a secondary constituent level of 300 mg/l for chloride,
- a primary constituent level of 4.0 mg/l for fluoride, and
- a secondary constituent level of 2.0 mg/l for fluoride.

Trinity Aquifer

TDS concentrations for groundwater samples from the Antlers and Twin Mountains Formations of the Trinity aquifer tend to increase downdip, towards the eastern part of the study area (Figure 15). Twenty wells exhibited TDS concentrations in excess of the secondary constituent level. Only 2 wells showed TDS concentrations above 2,000 mg/l. Chloride concentrations averaged 98 mg/l (Table 4), with 12 samples exceeding secondary constituent levels. Sodium concentrations had an average of 245 mg/l (Table 4). Nitrate concentrations averaged 1.00 mg/l (Table 4) with 5 samples exceeding primary constituent levels.

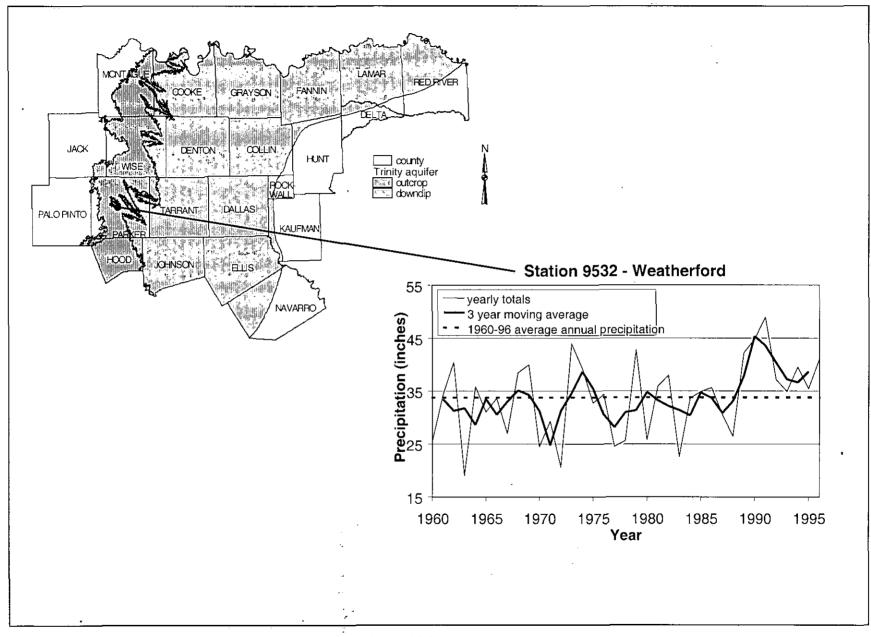

Figure 13. Precipitation at the Weatherford gage, 1960-1996.

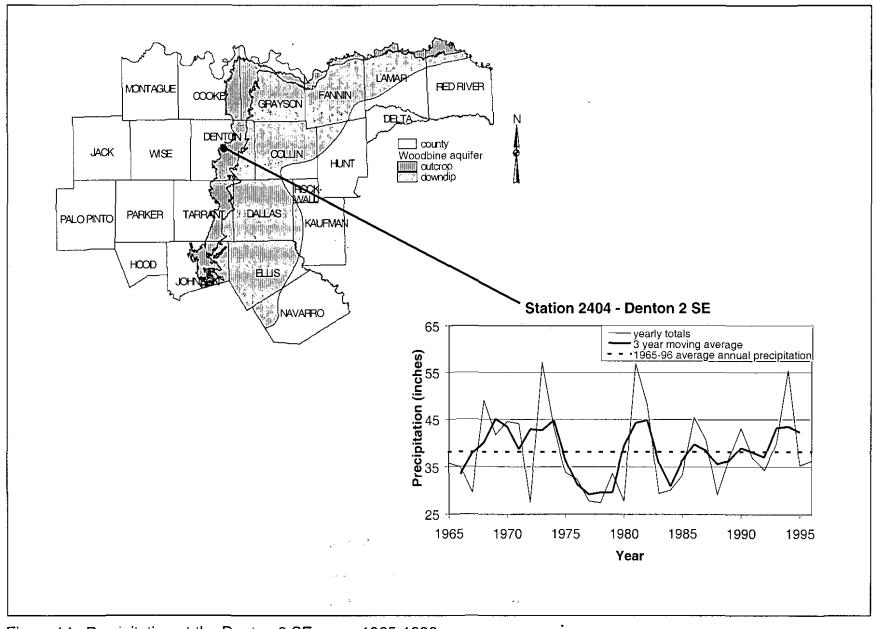

Figure 14. Precipitation at the Denton 2 SE gage, 1965-1996.

.

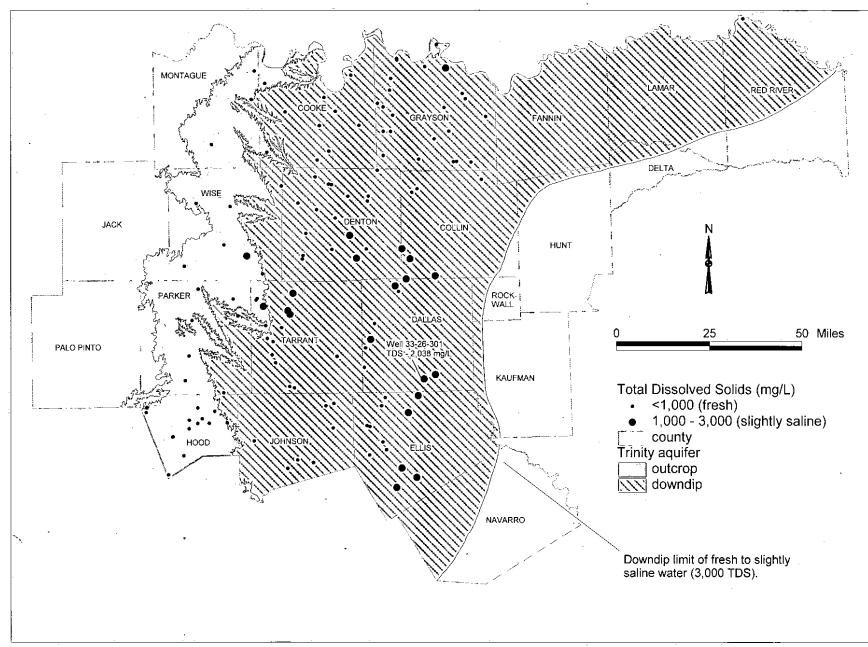

Figure 15. TDS concentrations in the Antlers and Twin Mountains Formations, Trinity aquifer, 1990-1998.

Parameter a serie de la serie	meter No. of Samples Average		<u>Minimum</u>	Maximum
		(mg/l)	(mg/l)	(mg/l)
TDS	131	717.67	221.00	2,038.00
Chloride	131	98.21	3.00	647.00
Sodium	131	245.26	8.80	657.00
Nitrate as N	129	1.00	<0.04	18.50
Sulfate	131	103.10	12.00	725.00
Fluoride	131	0.90	0.04	3.06

Table 4. Groundwater quality in the Antlers and Twin Mountains Formations, Trinity aquifer (based on data from TWDB 1998a).

Sulfate levels had an average of 103 mg/l (Table 4) with 4 samples exceeding 300 mg/l. The average fluoride concentration was 0.90 mg/l (Table 4) with the highest concentration reading 3.06 mg/l.

The highest TDS, chloride, and sodium levels were recorded in samples from well 32-06-104, located in north-central Tarrant County. The TDS concentration was 3,302 mg/l, chloride was 1,822 mg/l, and sodium was 1,210 mg/l. This area exhibits higher than normal TDS values possibly due to contamination from oil and gas production, as well as various other industries (Baker and others, 1990). Therefore, this well was not included in computing the average concentrations above.

Well 33-26-301, located in south-central Dallas County, is owned by the City of Lancaster and is currently used for backup purposes only. The TDS concentration was 2,038 mg/l, with chloride, sodium, and sulfate concentrations of 326 mg/l, 657 mg/l, and 725 mg/l, respectively, and probably reflects natural conditions.

The majority of samples exhibiting elevated TDS, chloride, sodium, and sulfate concentrations were collected from the Twin Mountains Formation. The areas showing high TDS concentrations include north-central Tarrant County and parts of Denton, Collin, Dallas, and Ellis Counties. Current TDS ranges are not significantly higher than historical values reported by Baker and others (1990).

In general, groundwater quality in the Paluxy Formation of the Trinity aquifer has remained acceptable throughout the study area. TDS concentrations for water samples collected from the Paluxy Formation averaged 607 mg/l (Table 5) with only 4 out of 51 wells sampled showing TDS concentrations above the secondary constituent level (Figure 16). The highest TDS concentration was 1,339 mg/l and was recorded at an irrigation well (18-58-503) located in Collin County. Chloride, sodium, sulfate and nitrate concentrations for this well were 31 mg/l, 431 mg/l, 590 mg/l and <0.04 mg/l, respectively.

Parameter	No. of Samples	<u>Average</u> (mg/l)	Minimum (mg/l)	<u>Maximum</u> (mg/l)
TDS	51	606.70	203.00	1,339.00
Chloride	[•] 51	36.08	4.00	273.00
Scdium	51	187.76	7.10	444.00
Nitrate as N	51	1.00	< 0.04	25.85
Sulfate	51	101.25	0.89	. 590.00
Fluoride	51	1.06	0.17	4.10

Table 5. Groundwater quality in the Paluxy Formation, Trinity aquifer (based on data from TWDB, 1998a).

Chloride and nitrate as nitrogen levels averaged 36 mg/l and 1 mg/l, respectively, and were all within primary constituent levels with the exception of one nitrate sample (Table 5). The highest nitrate concentration originated from well 32-10-603, located north of Weatherford in Parker County.

Sulfate and fluoride levels averaged 103 mg/l and 0.9 mg/l, respectively (Table 5). This well is designated as a public supply well and had a nitrate level of 25.85 mg/l. One sulfate sample (from well 18-58-503, described above) and one fluoride sample (from well 32-39-805, located in Johnson County) exceeded secondary constituent levels.

Woodbine Aquifer

Generally, TDS concentrations increase downdip towards the eastern part of the study area (Figure 17). Average TDS was 877 mg/l (Table 6) with the highest concentration (2,278 mg/l) from a public supply well (32-47-805) for the city of Grandview in southeastern Johnson County well. Chloride has an average concentration of 86 mg/l (Table 6) with 5 wells exceeding secondary constituent levels. Well 18-55-401, a public supply well owned by Caddo Basin Special Utility District located in Greenville (Hunt County), had the highest chloride concentration of 507 mg/l.

Parameter	No. of Samples	Average (mg/l)	<u>Minimum</u> (mg/l)	<u>Maximum</u> (mg/l)
TDS Chloride Sodium Nitrate as N Sulfate Fluoride	76 76 76 76 76 76 76	877.39 85.88 311.76 0.67 209.18 1.30	83.00 4.07 9.53 <0.04 5.42 0.24	2,278.00 507.00 825.00 10.41 1,263.00 6.27

Table 6. Groundwater quality of the Woodbine aquifer (based on data from TWDB,1998a).

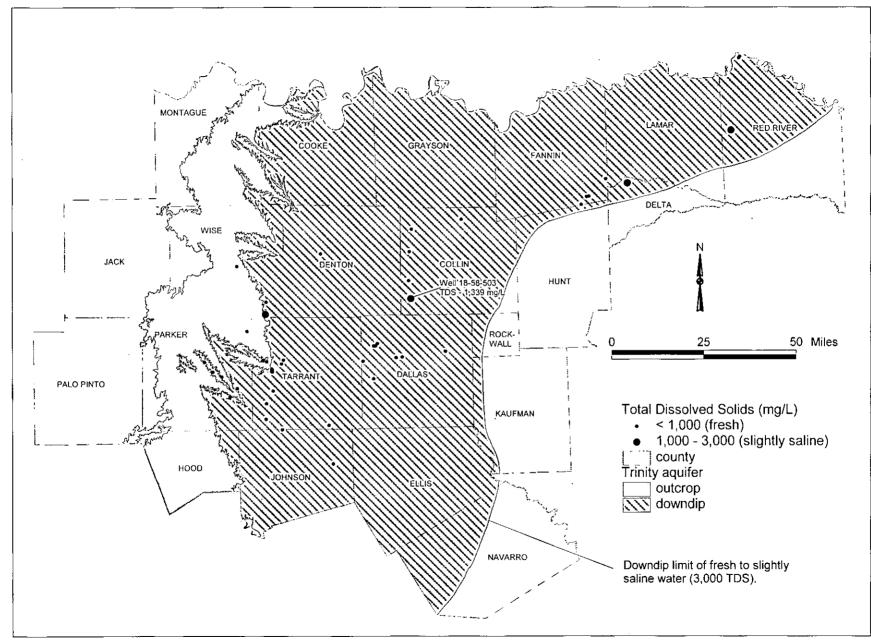

Figure 16. TDS concentrations in the Paluxy Formation, Trinity aquifer, 1990-1998.

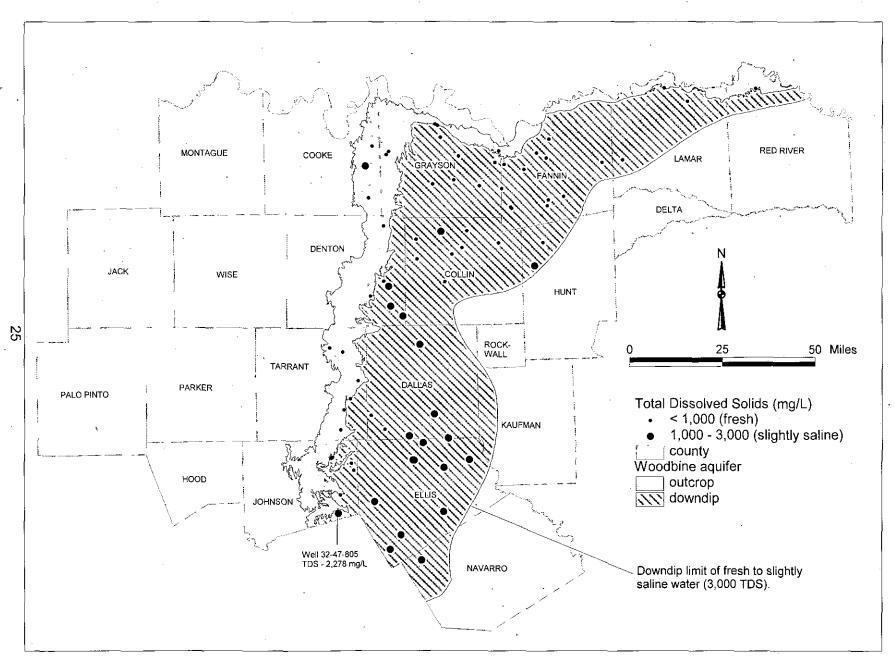

Figure 17. TDS concentrations in the Woodbine aquifer, 1990-1998.

Concentrations of nitrate (as nitrogen) averaged 0.67 mg/l and with one well exceeding primary constituent levels throughout the Woodbine aquifer. The highest nitrate concentration (10.41 mg/l) was recorded at a private well (18-13-803) in Grayson County.

Historically, the Woodbine aquifer has exhibited high sulfate levels associated with extensive lignite beds, especially in the southern outcrop areas of Tarrant and Johnson counties (Baker and others, 1990). Recent groundwater sampling results indicate that sulfate levels have remained elevated with 28 percent of the sampled wells exceeding secondary constituent levels. Elevated sulfate concentrations (>300 mg/l) were observed in 21 wells, with 4 wells containing concentrations above 500 mg/l. The wells are generally located downdip of the outcrop, towards the east.

WATER DEMANDS

Water demands are the projected needs for water in an area. Projected water demands are based on population projections, extrapolation of historical water use, and assumptions on water use.

Population

Population estimates by the TWDB are divided into 2 categories: major city and countyother. Cities that are county seats or have a population of at least 1,000 people are classified as major cities. All other cities and the rural county population are classified as county-other. Population estimates for both major city and county-other were divided using Geographic Information System (GIS) techniques on the basis of 1990 census data from the Bureau of Census statistics. Data for 1985 and 1995 (Table 7) are estimates based on county demographic data and Bureau of Census statistics for 1980 and 1990. Projected populations to 2030 (Table 7) are based on projections used in *Water for Texas, A Consensus-based Update to the State Water Plan* (TWDB, 1997).

North-central Texas is the most populated region in the State, containing 24 percent of the state's population with 4.12 million people in 1990 (TWDB, 1997). From 1985 to 1995, the population in the study area increased by 22 percent (Table 7), and is expected to increase 63 percent from 1995 to 2030 (Table 7). The 1985, 1990, and 1995 populations for cities, rural areas, and counties included in the study area, along with future projections through the year 2030, are shown in Table 7 (TWDB, 1998b).

Historical Water Use

An estimated total of 86,982 acre-feet of groundwater was pumped from the study area for municipal, manufacturing, steam-electric, mining, irrigation and livestock purposes in 1995 (Table 8). This reflects a 19 percent reduction in overall groundwater pumpage from the previous 10 years.

Table 8. Estimated groundwater pumpage, 1985-1995 (TWDB, 1998a).

Total groundwater and surface water use in 1985, 1990, and 1995 for the counties and cities in the study area is summarized in Table 9. The total water use was derived by determining the amount of water used for each category for the portion of each county that fell within the study area. These amounts were then proportioned into surface and groundwater use based on county-wide percentages (TWDB, 1998a).

Estimated total water use in the study area for 1995 was 1,072,879 acre-feet. Municipal water use was the largest water use category, and amounted to 903,896 acre-feet in 1995 (Table 9). Manufacturing and power (steam-electric) uses were second and third and amounted to 79,130 and 30,702 acre-feet, respectively. Estimated groundwater use for this period was 92,704 acre-feet, which amounts to approximately 9 percent of the total water use. From 1985 to 1995, it is estimated that groundwater use has declined by 14,661 acre-feet (14 percent). Estimated surface water use has increased by 133,668 acre-feet (16 percent) for the same period (TWDB,1998a).

Projected Water Demands

Total projected water demands for the year 2000 are 1,277,761 acre-feet (Table 10). About 6 percent of these demands (70,515 acre-feet) are expected to be met through groundwater supplies. Estimated total water demands for the year 2030 are expected to be 1,623,218 acre-feet. Less than 4 percent of these demands are expected to be supplied by groundwater. Between the years 2000 and 2030, projected groundwater use is expected to decline by approximately 11 percent from 70,515 to 62,763 acre-feet per year (TWDB, 1998c).

WATER AVAILABILITY

Water availability refers to the amount of water available for use in an area during drought of record conditions. Groundwater availability is determined by the amount of recharge and an acceptable amount of water removed from aquifer storage. Surface-water availability is defined by the firm yield of the reservoirs.

Groundwater Availability

The estimated annual groundwater availability of an aquifer is the estimated sustainable annual yield, or effective recharge, plus the acceptable amount of water that can be recovered from storage over a specified period of time. This estimate is made assuming withdrawals occur without causing irreversible effects such as land-surface subsidence or water-quality deterioration (Muller and Price, 1987). The estimated annual groundwater availability of the Trinity aquifer in the study area has been estimated to be about 63,000 acre-feet, which consists of 51,000 acre-feet of annual effective recharge and 12,000 acre-feet of groundwater recoverable from storage (Nordstrom, 1982). The annual effective recharge for the Trinity aquifer was determined using the trough method described by Klemt and others (1975).

Table 10. Projected water demands and supply sources for the study area (TWDB, 1998c).

Approximately 69,875 acre-feet of groundwater was pumped in 1995 (Table 8), which amounts to 140 percent of the estimated effective recharge. The estimated annual groundwater recharge and availability of the Trinity aquifer in the study area for the year 2030 has been estimated to be about 49,981 acre-feet (TDWR,1990). Estimated groundwater demands from the Trinity aquifer for 2000 are expected to be 50,337 acrefeet, subsequently declining to 42,491 acre-feet by 2030 (Table 10) (TWDB, 1998c). Based on these figures, projected demands will be less than estimated annual effective recharge. However, recharge is mainly limited to outcrop areas, so local overdraft of the aquifer in confined areas will continue to result in water-level declines.

The total estimated groundwater availability for the Woodbine aquifer is approximately 24,500 acre-feet (Nordstrom, 1982). The annual effective recharge to the Woodbine aquifer is approximately 24,000 acre-feet per year and an additional 500 acre-feet of recoverable usable water in storage (Baker and others, 1990). Approximately 17,107 acre-feet of groundwater was pumped from the Woodbine aquifer in 1995 (Table 8) (TWDB, 1998a). The total estimated annual groundwater recharge and availability in the Woodbine aquifer for the year 2030 is approximately 24,500 acre-feet (TDWR, 1990). Water demand projections estimate groundwater use to rise to 20,178 acre-feet by the year 2000 and to be 20,272 acre-feet per year in 2030, only slightly above the year 2000 projections (Table 10) (TWDB, 1998c). Based on these projections, groundwater demands from the Woodbine aquifer will remain less than the estimated annual effective recharge. As previously mentioned, recharge is limited mainly to outcrop areas. Overdraft of the aquifer can result in water-level declines in confined areas of the aquifer.

Even though regional annual effective recharge estimates exceed projected demands as a whole, Cooke, Denton, Grayson, Johnson, Parker, Tarrant, and Wise counties have experienced continuing local water-level declines in the Antlers, Twin Mountains, Paluxy, and Woodbine Formations. Based on the available estimates of effective recharge and estimated groundwater availability (Table 11) and historical groundwater pumpage and estimated supply (Table 12), groundwater use significantly exceeds available supply in Cooke, Denton, Grayson, Johnson, Parker, and Tarrant Counties. Continued production at similar rates could result in additional water level declines and depletion from storage. Continued conversion to surface water use will be necessary to compensate for the lack of groundwater availability in these areas. The 1997 State Water Plan (TWDB, 1997) for the above counties shows a gradual switch to surface water through 2030 to make up for a lack of groundwater availability (Table 13).

Surface Water Availability

There are 34 major surface water reservoirs with storage capacities greater than 5,000 acre-feet within the study area that contribute all or part of their respective yields to meet water needs (Figure 18). These reservoirs have a combined capacity of approximately 10,361,207 acre-feet of water and have a combined firm yield of approximately 1,875,138 acre-feet of water per year (Table 14) (TWDB, 1997).

Trinity River Basin	5,562,763	943,440
Brazos River Basin	717.570	<u>320,200</u>
Total for Study Area	10,361,207	1,875,138

Table 14. Reservoir capacity and firm yield (TWDB, 1997) (continued).

Based on current surface-water supplies, adequate amounts of water exist to supply the needs of the study area through the year 2030.

CONCLUSIONS

Water levels have remained relatively stable within the Antlers and Twin Mountains Formations of the Trinity aquifer since 1989 with the exception of Wise, Tarrant, and Johnson Counties. The southwestern part of Wise County has shown water-level declines of about 100 feet. Additionally, water-level declines of 200 feet have occurred in northeastern Tarrant County within the Dallas-Fort Worth metroplex. Minor waterlevel declines of approximately 50 feet have occurred in southern Johnson County. Southern Denton and Tarrant Counties, as well as northern Johnson County have experienced a rise in water levels from 50 to 200 feet.

Water sampling of wells in the Antlers and Twin Mountains Formations show TDS concentrations to be generally low in the outcrop area and elevated downdip to the east. Average TDS concentrations for the Antlers and Twin Mountains Formations were 718 mg/l. Average sodium concentrations were 245 mg/l.

Water levels in the Paluxy Formation of the Trinity aquifer have not changed significantly since 1989. The greatest water-level declines have occurred in southern Wise County and in Denton County where declines of 5 to 35 feet have been recorded. Water levels have risen 5 to 25 feet in most of Tarrant and Parker County. TDS concentrations averaged 607 mg/l in the Paluxy Formation. Average sodium concentrations were approximately 188 mg/l.

Water-level elevations for the Woodbine aquifer have been stable since 1989 with the exception of northern Collin County, the central to northeastern portion of Denton County, and northern Grayson County. Water levels have declined an average of 10 feet in parts of Denton and Collin Counties. Water-level declines of 60 feet have been observed in northern Grayson County.

The highest reported TDS concentrations within the study area are in the Woodbine aquifer, with most of the elevated concentrations occurring downdip. These high TDS concentrations are primarily due to high sulfate concentrations associated with extensive lignite beds. The Woodbine aquifer had an average TDS concentration of 877 mg/l with sodium concentrations averaging 311 mg/l and sulfates averaging 209 mg/l.

Groundwater use is projected to decline in the study area, which would allow for conservation of groundwater reserves. Continued conversion to surface water from groundwater should allow future demands to be met and is necessary to reduce waterlevel declines in Cooke, Denton, Grayson, Johnson, Parker, Tarrant, and Wise Counties. These projections suggest that adequate supplies of usable surface and groundwater exist to meet current and future needs of the study area through the year 2030.
