INTRODUCTION

PURPOSE

This report is submitted in partial fulfillment of the Texas Natural Resources Conservation Commission's requirement that the City of Houston complete a Water Conservation Plan. Specifically, this report documents the City of Houston's Reservoir Systems Operation Plan for operating the two reservoirs on the San Jacinto River, in order to optimize available water supplies.

ORGANIZATION OF REPORT

This first section presents background information on the City's surface water system and on the development of the Reservoir Systems Operation Plan. Section 2 presents a brief description of the two reservoirs on the San Jacinto River. Section 3 presents three alternative operating plans for the two reservoirs. Section 4 describes the development of the reservoir system model and the data which it uses. Section 5 presents the results of the simulation of the three alternative plans, and Section 6 presents recommendations, including a plan for the operation of the reservoirs to maximize the yield of the system.

BACKGROUND ON THE CITY'S WATER SUPPLY

Fresh water in the Houston area has primarily been obtained from groundwater. Because of the growing population and a growing industrial need for water, over-pumping of groundwater in the Houston area has become a serious problem. The water is being withdrawn from the ground faster than it can be recharged, causing ground surface subsidence in many areas.

To keep up with the growing need for water, and to decrease the reliance on groundwater, the City of Houston desires to increase the amount of surface water captured for use. This can be accomplished in a variety of ways, including trans-basin water transfers (such as from the Sabine, Trinity or Brazos Rivers), construction of additional reservoirs, or more efficient operation of existing reservoirs. This study focused on the third option, improving the efficiency of reservoir operations.

Section 2

RIVER AND RESERVOIR SYSTEM

The reservoir system shown in **Figure 2-1** is located on the San Jacinto River, which forms about sixty miles north of Houston, near Huntsville, Texas. It flows for about twelve miles enjoining several creeks until it flows into Lake Conroe, formed by an earth-filled dam northwest of Conroe, Texas (see below for lake details). The outflow of Lake Conroe becomes the West Fork San Jacinto River and traverses about thirty five miles before flowing into Lake Houston, east of Humble, Texas. The flow in the West Fork is enhanced by several tributary creeks joining the river, most notably Spring Creek near State Highway 59. Lake Houston receives flow from several tributaries, including the East and West Forks of the San Jacinto River, Caney Creek, and Luce Bayou. Luce Bayou has the possibility of being the conduit for water from the Trinity River that would be imported into Lake Houston. The San Jacinto River flows about another ten miles from the outflow of Lake Houston and empties into Scott Bay, east of Houston, which eventually empties into the Gulf of Mexico.

LAKE CONROE

Lake Conroe has a drainage area of 445 square miles and a surface area of 21,572 acres at maximum normal water level. The lake is formed by an earth-filled dam 11,300 feet long, including a controlled spillway. The dam was completed September 1, 1972, and deliberate impoundment began January 9, 1973. Water is used for municipal and industrial purposes in the Houston metropolitan area. A small diversion is also made for cooling purposes at the Gulf State Utilities Lewis Creek Reservoir. A spillway with five 40 x 30-foot tainter gates is located near the center of the dam. Low-flow releases are made through a separate multiple gate inlet tower. The tower has three gated controlled openings and one uncontrolled opening. It is connected to a stilling basin and a concrete weir by a 14-foot diameter conduit through the dam. Data regarding the dam and lake are given in **Table 2-1**.

Table 2-1
Lake Conroe—Dam and Lake Data

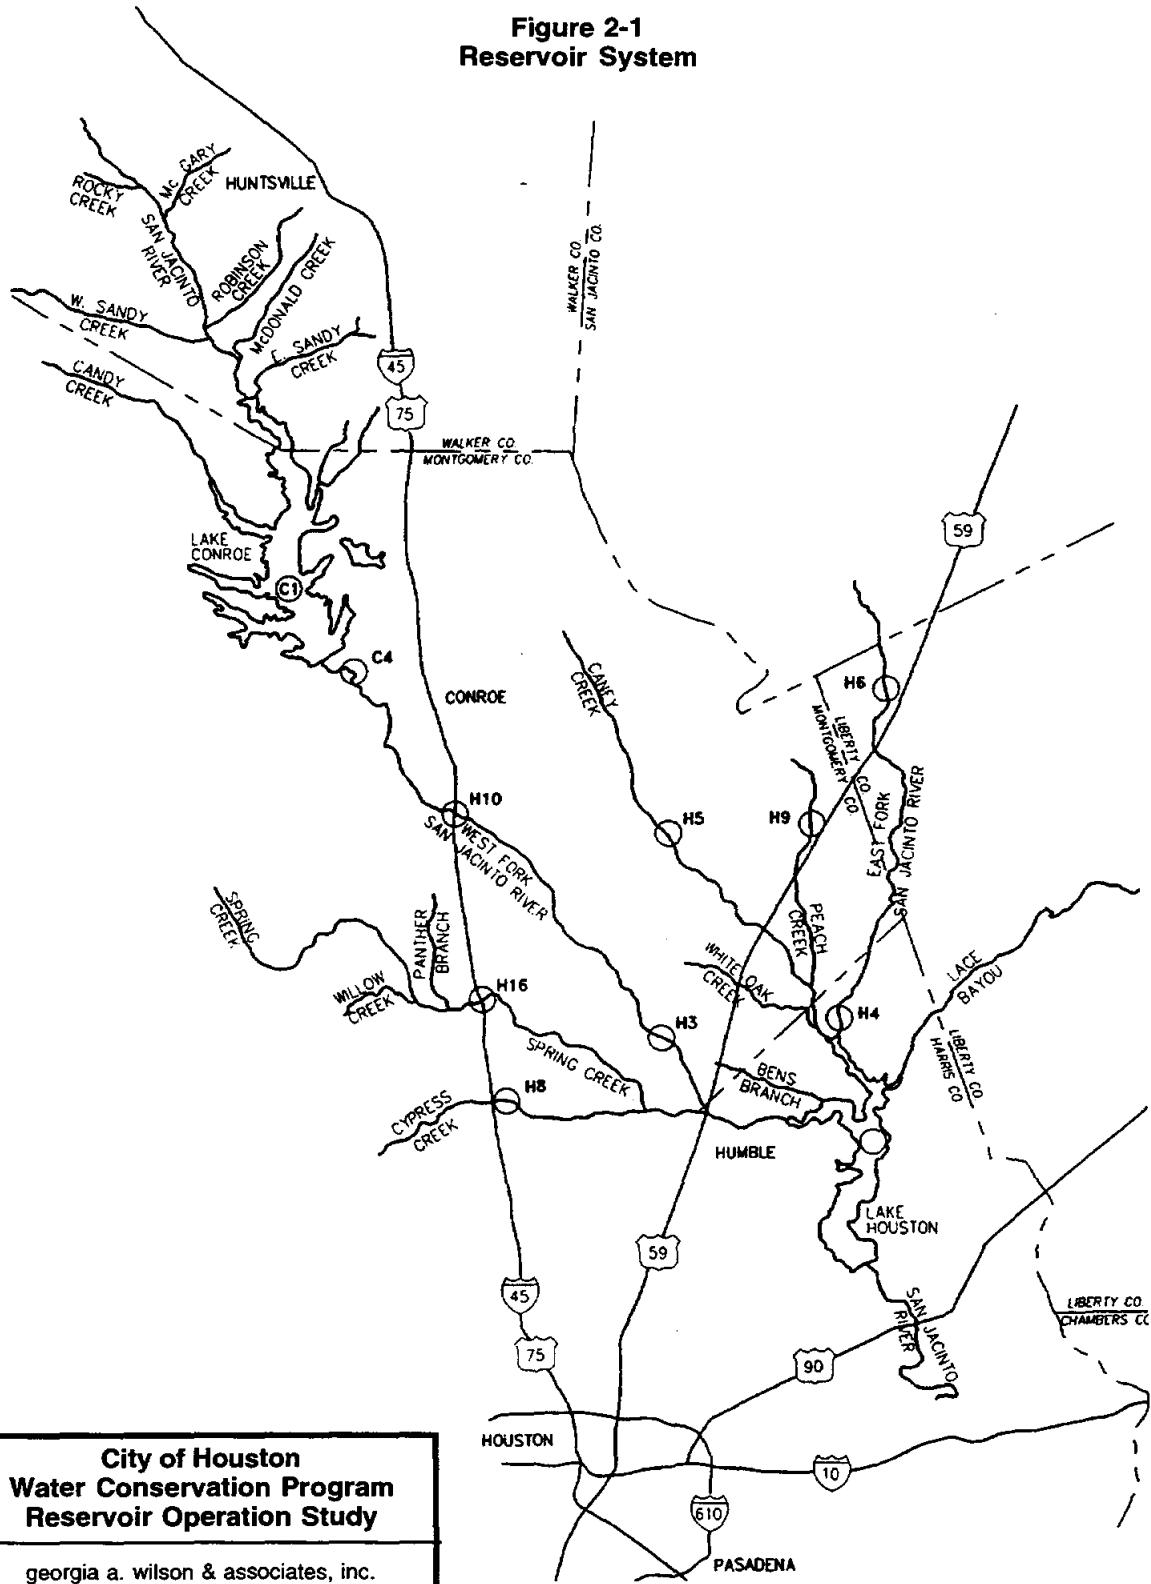

Description	Elevation (feet)	Capacity (acre-feet)
Top of Dam	212.0	
Top of Tainter Gates	202.5	462,600
Top of Conservation Pool (uncontrolled tower outlet)	201.0	430,260
Crest of Spillway (sill of tainter gates)	173.0	64,960
Lowest Gated Outlet (invert)	144.5	300

The maximum normal water level of Lake Conroe is elevation 201.0 with a capacity of 430,260 acre-feet. The maximum contents of the lake, 512,000 acre-ft (204.66 ft), occurred on May 22, 1983. The minimum contents, 336,900 acre-ft (196.17 ft), occurred January 11, 1989.

Section 2

HISTORICAL WATER USE PATTERNS

The City of Houston (COH) owns 67% and the San Jacinto River Authority (SJRA) owns 33% of Lake Conroe. The reservoir is operated by the SJRA. The current SJRA operations practice is the following:

"Water is released when called for by the City of Houston after Lake Houston reaches approximately 2.0 feet below spillway level, and at the rate called for by COH. Releases are made through the upper gates until it becomes necessary to open the next lower one to achieve the required flow."

The SJRA has first priority for use of the water in the lake. The first releases of the month are charged to their account, up to their permitted volume, then the water is charged to COH. The maximum permitted release rate is 700 cfs.

LAKE HOUSTON

Lake Houston has a drainage area of 2,828 square miles and a surface area of 13,068 acres at maximum normal water level. The lake is formed by two earth-filled embankment sections and a 3,160-foot long concrete spillway midway between the embankment sections. The dam was completed and storage began on April 9, 1954. The spillway includes two tainter gates, 18.0 x 20.5 ft., that can be used for control of releases below a maximum gage height of 44.5 ft. and above a minimum gage height of 28.0 ft. In addition, there is a 36-inch diameter sluice gate that is used for low-flow releases. Water is used for irrigation, municipal, and industrial supply in the Houston metropolitan area. Data regarding the dam and lake are given in **Table 2-2**:

Table 2-2
Lake Houston—Dam and Lake Data

Description	Elevation (feet)	Capacity (acre-feet)
Top of Dam	63.0	
Crest of Spillway	44.5	133,900
Crest of Tainter Gates (sill)	28.0	22,800
Lowest Gated Outlet (invert)	22.0	6,180

The maximum contents of the lake, 219,400 acre-ft (elevation 49.6 ft), occurred on May 19, 1989. The minimum contents, 53,380 acre-ft (elevation 34.08 ft), occurred on December 1, 1971.

COH has a right to divert 149 mgd from Lake Houston. SJRA has a right to divert 50 mgd from the lake. Currently, COH has total (Conroe and Houston) water rights from the San Jacinto River for a maximum of 19,500 acre-feet per month. SJRA holds total water rights from the San Jacinto river for 7,500 acre-feet per month. All of the rights are currently withdrawn from Lake Houston.

Section 3

ALTERNATIVE OPERATIONS PLAN

The operations target and plan of a reservoir system is defined within a set of operational criteria. These criteria include reserve storage levels, release rates, and withdrawal rates. Criteria are established based upon issues that may include impacts upon recreation and the environment, water quality, reliability of water supply, and other physical or institutional operational constraints. Each issue has the potential to affect how the reservoirs are operated, and thereby affect how much water is available to meet water supply needs. For example, if a recreational minimum storage constraint is imposed, releases and diversions might be restricted when the water level approached that minimum storage. This could reduce the water supply yield of the system, but the trade-off of recreational benefits might make this reduction worthwhile.

In the case of the City of Houston's reservoir operations plan, there are currently no significant operational criteria other than the maximization of water supply. Three alternative operational plans were developed to maximize the yield of the system.

The three scenarios investigated in this study are:

- Existing operations to maximize firm yield with reserve storage
- Modified operations to maximize firm yield without reserve storage
- Modified operations to maximize average yield with reserve storage

The reserve storage constraint is controlled by setting a relatively high minimum storage volume for Lake Houston. When the storage falls below this level, the model will not release water from the lake. Correspondingly, as Lake Houston storage drops close to this level, higher calls are made from Lake Conroe. A higher reserve storage volume will save a designated amount of water for critical drought periods. Recreational and environmental benefits could also be protected by setting a high minimum storage volume.

The downstream call volume is the storage volume of Lake Houston that will cause Lake Conroe to release water from storage, if any is available. This "call" is made in order to increase the volume of water stored in Lake Houston. Under current operations, water is called from Lake Conroe when Lake Houston is drawn down 2 feet below the spillway crest. This corresponds to a Lake Houston call volume of 113,610 acre-feet. By lowering this call volume, Lake Houston's storage will fluctuate more than if the call volume was higher. Lake Conroe's storage would be more stable if the Lake Houston call volume was lowered, because it would have to release water less often.

EXISTING OPERATIONS FOR FIRM YIELD WITH RESERVE STORAGE

This alternative is patterned after the current operating procedure for the lakes. The minimum pools are set so that there is a reserve storage pool, and downstream call volume is set at the level that is currently being used by SJRA. Both firm and average yield are evaluated so that comparisons can be made to the other operating plans.

Section 3

ALTERNATIVE OPERATIONS PLAN

OPERATIONS TO MAXIMIZE FIRM YIELD WITHOUT RESERVE STORAGE

This operating plan tested the reservoir system to estimate the largest firm yield possible. There are no reserve storage, water level, minimum flow, or other limits that may adversely affect the firm yield of Lake Houston. The maximum yield was found by setting the lowest possible storage limits on the lakes and flows, while increasing Lake Houston diversions until they could not be delivered.

OPERATIONS TO MAXIMIZE AVERAGE YIELD WITH RESERVE STORAGE

This operating plan evaluated the optimum average yield of Lake Houston while retaining reserve pools in Lakes Houston and Conroe to be used during extended low flow periods. The plan was developed by setting the same limit on the minimum pool levels of the lakes as in the existing operations and adjusting the downstream call volume until the highest average yield was found.

Section 3
ALTERNATIVE OPERATIONS PLAN

OPERATIONS TO MAXIMIZE FIRM YIELD WITHOUT RESERVE STORAGE

This operating plan tested the reservoir system to estimate the largest firm yield possible. There are no reserve storage, water level, minimum flow, or other limits that may adversely affect the firm yield of Lake Houston. The maximum yield was found by setting the lowest possible storage limits on the lakes and flows, while increasing Lake Houston diversions until they could not be delivered.

OPERATIONS TO MAXIMIZE AVERAGE YIELD WITH RESERVE STORAGE

This operating plan evaluated the optimum average yield of Lake Houston while retaining reserve pools in Lakes Houston and Conroe to be used during extended low flow periods. The plan was developed by setting the same limit on the minimum pool levels of the lakes as in the existing operations and adjusting the downstream call volume until the highest average yield was found.

Section 4 **DEVELOPMENT OF THE** **RESERVOIR OPERATIONS MODEL**

A computer model of the reservoir system was developed to simulate the storage in Lake Conroe and Lake Houston, and the flows between the lakes. It was created using historical data, estimated flow relationships, and predicted demands. Month-by-month water yield can be calculated for each of the operational alternatives, providing a means for optimization. The following sections give a detailed account of the steps performed in the development of the model. The steps were:

1. Data collection
2. Hydrological analysis
 - Naturalization of data sets
 - Regression analysis
 - Creation of expanded data sets
 - Calculation of the water gained from the outflow of Lake Conroe to the inflow of Lake Houston
3. Operational simulation
 - Historical simulation
 - Evaluation of alternatives

The study period of the project is from 1950 to 1994. Many of the data sets did not cover the whole study period. Depending upon the data set, the data may have been extrapolated, regressed against another complete set and expanded, or used only in the period when the data were available.

DATA COLLECTION

The flow model created for this study required a large amount of historical data. Not only are the data used as input to the model, but many of the data sets were used to create new data sets. The historical data are also used as a way to validate the model, to see if the model provides reasonable results. Almost all of the manipulations and results of the model are dependent upon the reliability of the data. The data were primarily obtained from regulatory sources, such as SJRA, USGS, and TNRCC.

Flow Data

Flow data were obtained from the United States Geological Survey (USGS). They operate several flow gaging stations in San Jacinto drainage basin. Information was requested for the gages shown in **Table 4-1**.

Section 4
DEVELOPMENT OF THE
RESERVOIR OPERATIONS MODEL

Table 4-1
San Jacinto Flow Gaging Stations

Code	USGS #	Location
C4	08067610	West Fork @ FM 105
H1	08069500	West Fork @ Humble
H3	08068090	West Fork near Porter
H4	08070200	East Fork @ New Caney
H5	08070500	Caney Creek
H6	08070000	East Fork @ Cleveland
H8	08069000	Cypress @ Westfield
H9	08071000	Peach Creek
H10	08068000	West Fork near Conroe
H12	08071280	Luce Bayou
H16	08068520	Spring @ Spring
H22	08072050	San Jacinto near Sheldon
H23	08071500	San Jacinto near Huffman
H24	Unknown	West Fork near Humble

See **Figure 2-1** for the location of the stream-flow gages. All data for the period of record were received from USGS with the exception of H24, which was not available. The data are average monthly discharges with the units of cubic feet per second. All of the above gages are located above Lake Houston, but below Lake Conroe, with the exception of H22 and H23. The upstream data are useful in estimating how much the West Fork San Jacinto River and Lake Conroe contribute to the inflow of Lake Houston. The H23 data period of record is 1937 to 1953, which is not very useful for this study, and H22 data were stage, not discharge, from 1993 to 1995, also not very useful. These were the only USGS gages located below Lake Houston, therefore, there were no useable river gage flow data available below Lake Houston. This added a significant degree of difficulty to the hydrological analysis because the outflow of Lake Houston is required to most accurately estimate the Lake Houston inflow.

Diversion Data

TNRCC Data

Diversion and water rights data were provided by the Texas Natural Resources Conservation Commission (TNRCC). The TNRCC grants and administers the surface water rights in Texas. The request was made for water rights summaries of two known water rights numbers (#4964 & #4965) and any other rights in the San Jacinto River Basin. **Table 4-2** shows the water rights' summaries that were received.

Section 4
DEVELOPMENT OF THE
RESERVOIR OPERATIONS MODEL

Table 4-2
San Jacinto Water Rights

W.R. #	Owner	Stream (Source)
1433-1342	SJRA	San Jacinto
2108B	SJRA	W.F. San Jacinto
4963	SJRA, et al.	W.F. San Jacinto
4965	COH	San Jacinto
4964	SJRA	San Jacinto
1505-1422	SJRA	San Jacinto
2109A	Nevin Marr	N. PR Medina
1743	LL Gilger	Pecan Bayou
1505	DJ Burda, et al.	N. Llano
2108	BH Gaskin	Rocky Creek
1433	TJ Stehling	Barons Creek

Of the above reports, numbers 1433-1342, 2108B, 4963, 4965, and 4964 have significant data. The others are either out of the study area or have insignificant (or zero) diversions. The data have units of acre-feet and are given in yearly total diversions. Most years are also broken down into monthly total diversions.

USGS Data

The TNRCC data were compared to diversion data reported on USGS yearly water contents records for Lake Houston. After examining the data and speaking with personnel from both agencies, the USGS data were determined to be more complete and reliable, and were used as the Lake Houston diversion data. The data are not broken down into specific users or uses, but only the totals are needed for historical water balance purposes.

Meteorological Data

In creating the water balances on the lakes, several major forms of water gain and loss were accounted for in the model. Measured flows, if available, are an excellent way to obtain inflows and outflows to the lakes, but there are also other water gains and losses. The most significant of these are meteorological gains and losses from precipitation and evaporation.

Precipitation Data

Precipitation data for Lake Houston were obtained through the Southern Regional Climate Center (SRCC) in Baton Rouge, Louisiana, and The Weather Almanac published by Gale Research, Inc. The data from SRCC were received as daily rainfall amounts, in inches, at Houston Hobby Airport from 1941 to 1994. The Weather Almanac data are monthly precipitation (inches) at Houston

Section 4 **DEVELOPMENT OF THE** **RESERVOIR OPERATIONS MODEL**

Hobby Airport (1961-1968) and Houston Intercontinental Airport (1969-1990). Lake Houston is closer to Houston Intercontinental than Houston Hobby, so the data from Houston Intercontinental were used when available, otherwise the Houston Hobby data were used.

Precipitation data for Lake Conroe were obtained through SJRA. The data were reported as monthly depths in inches.

Evaporation Data

Evaporation data for Lake Houston were also obtained through SRCC. This is not a recorded data set but is calculated by SRCC. The data were estimated from the monthly average atmospheric conditions in Houston.

The same monthly evaporation data were used for Lake Conroe, with a factor of 1.05 applied.

Reservoir Data

End of Month (EOM) Storage

Reservoir storage data for both Lake Conroe and Lake Houston were obtained from USGS. The data were given as storage on the last day of the month in acre-feet. The data cover the period from the filling of the lakes (Houston-1954, Conroe-1974) until 1995. During model generation it was found that the EOM storage data were not precise enough to accurately predict the monthly flow from the Lake Houston spillway. Lake Houston daily storage data were subsequently obtained from USGS to calculate daily spills. The daily spills were accumulated for each month.

Area-Capacity Tables

Area-capacity tables were necessary to calculate surface area and water surface elevation information about the lakes from the storage volume data. The tables are graduated by elevation, and give the storage and surface area of the lake at a given elevation. There are two Lake Houston tables used for the historical analysis of Lake Houston, one to be used from 1954 to 1965 and the other from 1965 to 1995. A third table relating gage height to storage, taken from a Texas Water Development Board (TWDB) 1994 survey, was used during the simulated operations of the lakes. All three tables were obtained from USGS. The San Jacinto River Authority (SJRA) provided an area-capacity table for Lake Conroe.

HYDROLOGICAL ANALYSIS

The hydrological analysis was performed to create data that were required in the simulation model. These data sets included inflows to Lake Conroe, and total inflow and gain at Lake Houston.

Lake Conroe Water Balance

The first step was to modify or expand existing data sets C-4 and H-10 (locations shown on **Figure 2-1**) to represent natural flows. Natural flows are the river flows that would have existed if

Section 4

DEVELOPMENT OF THE RESERVOIR OPERATIONS MODEL

Lake Conroe had not been built. This data modification was performed by removing the lake effects from the recorded data sets, a process called "naturalization" throughout this report. In performing regression analyses to extend hydrological data sets, it is critical that the data sets represent natural conditions.

Naturalization of C-4 and H-10

Gages C-4 and H-10 are downstream of Lake Conroe on the West Fork of the San Jacinto River. C-4 is just below the spillway and H-10 is about ten miles downstream. Data set H-10 is complete for the entire study period, 1950 to 1994. Data from gage C-4 are complete from the filling of Lake Conroe in 1973, to the end of the study. In order to extend the C-4 data and to determine the monthly amount of water that flows into Lake Conroe, the data sets have to be naturalized. The naturalization process is a water balance for Lake Conroe that removes the lake effects from the recorded flow data. Data sets C-4' and H-10' were created representing the theoretical flow at the gages as if Lake Conroe had not been constructed. The effects of the lake were removed by factoring out changes in historical water volume and meteorological effects.

A change in storage volume of the lake will affect the recorded flow. If the change is positive, the gaged flow will be lower than the natural flow; and conversely, if the change is negative, the gaged flow will be greater than the natural flow would have been.

The meteorological effects on the recorded volume of water can also be removed. The monthly precipitation and evaporation depths can be multiplied by the surface area of the lake to obtain precipitation and evaporation volumes. The precipitation volume is subtracted from the river flow. If the lake was not present, the rainfall would have been captured by foliage or infiltrated into the ground and would not have added significantly to the river flow.

The evaporation volume has the opposite effect on the flow data. Therefore, the evaporation volume is added to the measured flow because it was water that would have stayed in the system if the lake had not been constructed.

Any water that is diverted, for municipal, industrial or irrigation use, is also added back into the naturalized stream-flow. The general equation for the naturalization of gage C-4 is:

$$C-4' = C-4 - S - (\text{Precip.} \times A) + (\text{Evap.} \times A) + \text{Diversion}$$

where S is the end of month storage, and A is the Lake Conroe surface area corresponding to that storage. The flow rates were converted to monthly volumes (by multiplying by the number of seconds in the month, and dividing by 43,560) in the above equation, giving C-4' as a total volume of flow in the month. The same procedures were applied to create H-10', substituting H-10 for C-4. Appendix A presents the complete spreadsheet (with formulas) used to create C-4'.

A double mass analysis was used to check the relationship between flows at C-4 and flows at H-10. A double mass analysis compares the cumulative flow at one gage with the cumulative flow at another. It will help in discerning data inconsistencies, shifts, and trends. The double mass curve for gages C-4 and H-10 is shown in **Figure 4-1**, and displays no significant problems.

Section 4

DEVELOPMENT OF THE RESERVOIR OPERATIONS MODEL

Regression Analysis and Creation of C-4' (1950-1973)

Since gage C-4 was constructed after Lake Conroe was built, the naturalized C-4 data set (C-4') only has values from 1973 to the present. Gage H-10 has been in operation throughout the study period, therefore a naturalized H-10, H-10', was created for the entire period. A regression analysis was then performed to develop a relationship between C-4' and H-10' for the period when both data sets were available. The resulting equation:

$$(C-4') = 0.479 \times (H-10') + 909 \text{ acre-ft/month}$$

was applied to the H-10' values before gage C-4 began operation, yielding C-4' (1950-1973). This simulates natural flow at the gage before Lake Conroe was built. The equation was also used to fill any gaps in the C-4' (1973-1994) data. This created a complete data set, C-4', for the naturalized outflow of Lake Conroe for the study period (see Appendix A).

Lake Houston Water Balance

The next step was to determine the amount of water that flows into Lake Houston. Once the Lake Houston outflow was determined, the inflow could be found by assuming that the water that was taken from the lake (releases, spills, diversions, and evaporation) must equal the water entering the lake (inflow and precipitation).

Because of the lack of a gaging station downstream of the Lake Houston spillway, and because the upstream gages only cover about 60 percent of the drainage area, the water balance for Lake Houston was not as straight-forward as that of Lake Conroe.

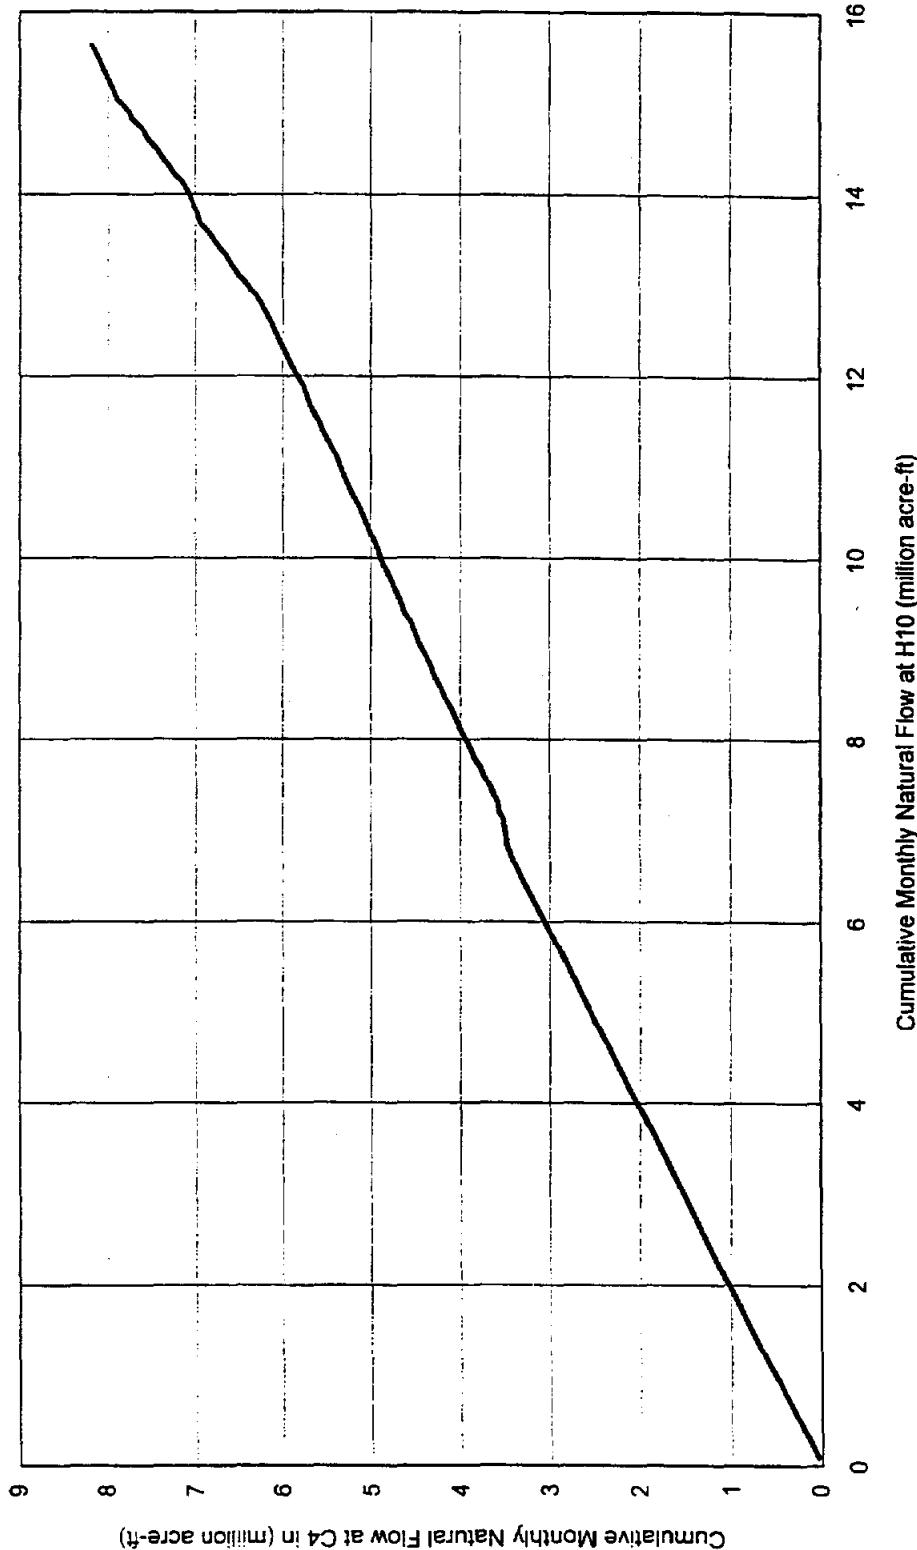

To estimate the total inflow into Lake Houston, the estimated flow over the spillway was calculated using daily reservoir storage data, area-capacity elevation tables and a spillway rating table. First, the daily storage of the lake was converted to daily stage, using a capacity vs. elevation table. Next, the daily stage was compared to the spillway rating table to estimate the discharge rate. The discharge rate was converted to a daily total discharge and then summed for each month. It was assumed that, other than diversions, the spillway discharge was the only outflow from Lake Houston.

Section 4

ALTERNATIVE CONSERVATION MEASURES

Figure 4-1

Double Mass Analysis—Naturalized Flow at C4 vs. Naturalized Flow at H10

Section 4

DEVELOPMENT OF THE RESERVOIR OPERATIONS MODEL

This method of estimating the outflow of Lake Houston, although the best method using the available data, did not yield acceptable results. Because of the extremely large width of the Lake Houston spillway, the application of the daily stage data with the elevation-discharge curve did not yield flows representative of the average daily spill. The calculated spills were approximately 60 percent greater than the average runoff per square mile computed for the upstream gages. Also, a double mass analysis of the calculated lake Houston inflow (using the spill calculation) against the sum of the upstream gages, showed a significant skew towards higher inflows in the last twenty years. This may be caused in part by subsidence in the Lake Houston area. The double mass curve for computed Lake Houston inflow (using the spill calculations) versus the sum of the upstream gages is shown in **Figure 4-2**. The bend in the curve is indication of an inconsistency in the calculated inflow data.

To avoid a significant over-estimation of Lake Houston inflow, an alternate method for estimating the inflow to Lake Houston had to be developed. Freese and Nichols, Inc. developed a method in a 1966 study that estimated the Lake Houston inflow by multiplying the sum of five other gaged tributaries of the lake by a constant factor. All except one of these gages are still operating. The constant factor developed by Freese and Nichols was recalculated to apply to only the remaining four gages. The tributaries are Caney Creek, Cypress Creek, West Fork San Jacinto River, and Spring Creek, gages H-5, H-8, H-10, and H-16, respectively. These tributaries are the closest gaging stations, with full data sets, to Lake Houston, see **Figure 2-1**. The constant factor of 1.57 represented the average ratio of flows in the four other gages versus the total inflow to Lake Houston. For this model, the inflow to Lake Houston was calculated as the greater of the following two relationships:

$$IN_H = 1.57 \times \Sigma(4 \text{ gages}) \quad \text{or}$$

$$IN_H = C-4' + 99 \text{ acre-feet}$$

The second equation is a safety factor to make sure the calculated inflow to Lake Houston is larger than the outflow from Lake Conroe. The naturalized flow at the H-10 gage was used in place of the recorded data, to take out the effects of Lake Conroe storage.

The naturalized Lake Conroe outflow ($C-4'$) was then subtracted from the calculated Lake Houston inflow (IN_H) to determine the gain between Lake Conroe and Lake Houston:

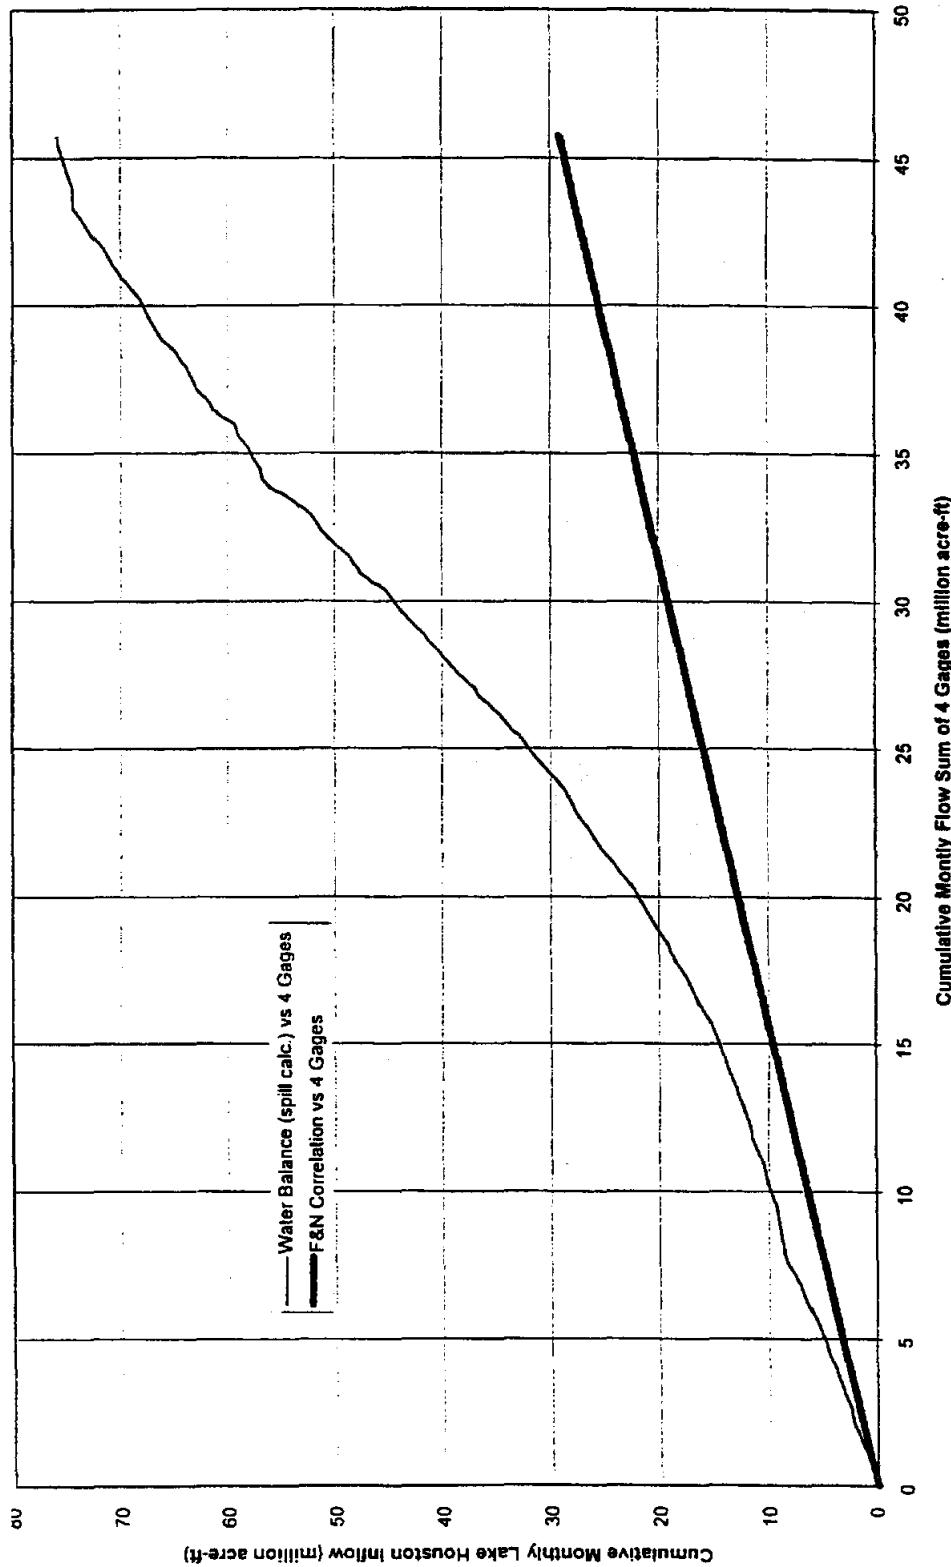

$$GAIN = IN_H - (C-4')$$

GAIN represents the amount of water that flows into Lake Houston that is not attributable to the flow out of Lake Conroe. This is the monthly minimum amount of inflow that Lake Houston will receive, independent of the Lake Conroe operations. The GAIN data set was then regressed against the sum of the four indicator gages, so that any missing or unreasonable GAIN values could be replaced with data from the regression results. See Appendix B for the complete spreadsheets and formulas used to calculate GAIN.

The created data sets were checked by various statistical methods and showed an acceptable correlation.

DEVELOPMENT OF THE
RESERVOIR OPERATIONS MODEL

Figure 4-2
Double Mass Analysis Of Lake Houston Inflow By Water Balance And Correlation

Section 4

DEVELOPMENT OF THE RESERVOIR OPERATIONS MODEL

MODEL DEVELOPMENT

The San Jacinto River Reservoir Operations Model is a spreadsheet that simulates the combined operations of Lake Conroe and Lake Houston. It uses 45-years of historically-based hydrological data to show how the monthly storages, flows, and yield will change with a change in the operating criteria. The inflows and outflows of both lakes are calculated and combined with the meteorological effects in order to see if there is water available for the desired diversions. Appendix C presents a complete printout of the model for one simulation run of each of the three operational alternatives. Appendix C also presents an explanation of the column-by-column manipulations used in the spreadsheet.

Model Parameters

The model begins the study period with both lakes at maximum level and uses recorded and estimated data, such as C-4, GAIN, precipitation, evaporation, etc., to estimate the storage volumes, inflows and outflows of both lakes over the period. There are several parameters, or limits, that can be modified to reflect operational changes or other model refinements. These are shown in bold at the top of the columns on the model spreadsheet and are explained below.

Lake Conroe

Available Water. The maximum available water. This includes last month's End of Month Storage, plus this month's inflow to the lake. The limiting parameter is meant to allow full use of all monthly inflow and still keep the reservoir full at the end of the month.

Usable Water. The Available water, less the amount lost to evaporation and gained from precipitation. The parameter value is set to reflect the maximum end-of-month storage plus the maximum monthly diversions and calls.

Diversions. The monthly amount of water that is required to be diverted from Lake Conroe. This is currently set at a constant 467 acre-feet per month to represent the maximum average monthly Gulf States power diversions. Other values could be used should the City desire to simulate a City or SJRA diversion directly from Lake Conroe.

D.S. Calls. This represents the storage volume of Lake Houston at which water is requested from Lake Conroe to alleviate the low storage. When the EOM storage of Lake Houston falls below the value at the top of the column, the spreadsheet will check whether Lake Conroe needs to release available water. If not, no forced releases from Lake Conroe storage will be made. The call formula also restricts the Conroe releases so that a maximum of 50 percent of the water remaining in storage can be released in any given month.

EOM Storage. The storage volume remaining in the lake. The limiting value is set as the lake capacity at the top of the spillway.

Section 4

DEVELOPMENT OF THE RESERVOIR OPERATIONS MODEL

Total Outflow. This is the total outflow from the lake. The parameter can be set to the minimum amount of outflow from Lake Conroe. This can be governed by an in-stream flow requirement. It is currently set to zero.

Luce Bayou Transbasin. The monthly amount of water that SJRA will transport into the system from the Trinity River. This is currently set to zero.

Lake Houston

Available Water. The maximum available water. This includes last month's End of Month Storage, plus this month's inflow to the lake. The limiting parameter is meant to allow full use of all monthly inflow and still keep the reservoir full at the end of the month.

Usable Water. The Available water, less the amount lost to evaporation and gained from precipitation. The parameter value reflects the maximum end-of-month storage plus the maximum monthly diversions.

Diversion SJRA. The desired monthly SJRA diversions. This is currently set to a constant 7,500 acre-feet per month.

Diversion COH. The desired monthly COH diversions, currently set to a constant amount equivalent to the City's total water right, or 19,500 acre-feet per month.

EOM Storage. The storage volume remaining in the lake. The limiting value is set to the capacity at the top of the spillway.

Min. Storage. The minimum storage volume for Lake Houston. The value is set by the invert of the lowest gated outlet or could be based upon other water quality or emergency storage guidelines.

Model Application

The model gives a month-by-month accounting of the storage volumes in both lakes, the flow between the lakes, and diversions from each lake, along with all the data that were used as input data. Also tabulated are the minimum, maximum, and average value for each data type during the study period.

Firm yield. The firm yield is the largest constant volume of water that can be diverted from Lake Houston each and every month. This is the monthly amount of water that the COH and SJRA can guarantee to provide to their customers. The Lake Houston firm yield can be found by keeping all inputs constant and varying the Lake Houston diversions, the firm yield is the largest sum of COH and SJRA diversions that can be met 100% of the time.

(Note: The firm yield predicted by the model is based upon the estimated San Jacinto River flows over the past 45 years. In more severe droughts, or critically dry periods lasting longer than those in this time period, the firm yield could be lower.)

Section 4

DEVELOPMENT OF THE RESERVOIR OPERATIONS MODEL

Average Yield. The average yield is the average monthly volume that can be diverted from Lake Houston over the 45-year modeled period.

Operational Limits. Several of the operational limits can be adjusted in an attempt to increase the firm yield. The limits may also be changed for other reasons such as environmental regulations, water quality constraints, or a change in the physical limits of the lake. Listed below are the limits that can be adjusted.

Lake Houston Minimum Storage. The storage has a physical limit, the bottom of the lowest outlet. No water that is lower than this level can be released from the lake. One suggested operation of the lake would put the minimum operational storage at the level where the surface area of the lake is 50% of the full capacity's surface area. A higher minimum storage will retain a larger amount of reserve water that can be used during extended periods of low flow. A lower minimum storage limit will allow the lake to be drained lower during normal operations.

Diversions from Lake Conroe. The diversions from the lake are for industrial, municipal, and irrigation uses. The value is a constant value to be taken from the lake every month. The maximum volume of water being taken by Gulf States Utilities is currently used in the simulations. These values can be varied to reflect historical or current operations, future projections, or any other anticipated diversion situations.

Downstream Call. The call for water needed by Lake Houston allows Lake Houston to obtain extra water from Lake Conroe. The parameter represents a Lake Houston storage volume. When Lake Houston EOM storage is below this level, Lake Conroe will release the water to Lake Houston, if needed and available. The current operating procedures call water from Lake Conroe when the Lake Houston water level falls below two feet lower than the spillway. This is one of the more flexible parameters when optimizing the water yield.

Total Outflow. The minimum total outflow parameter is a way to set minimum in-stream flow. Since there are currently no guidelines, the minimum is set to zero. The minimum can be increased if regulations or operational procedures are enacted for environmental, recreational, or other reasons.

SJRA and COH Diversions. The diversions from Lake Houston are separated into SJRA and COH diversions. The SJRA diversions are primarily used for industrial purposes, while the COH diversions are primarily for domestic and irrigation applications. The values entered are maximum target values, and are met if the lake has water available. In periods of shortage the total monthly diversions are rationed to COH and SJRA according to their ownership percentages. The model will request the entire amount as stated on their water rights (27,000 acre-feet/month) and divide the amount accordingly. If the entire 27,000 acre-feet cannot be delivered, the top of column parameter volume can be lowered until the amount can be delivered every month (firm yield).

The model begins calculations with both reservoirs at full capacity. This can be changed by entering any desired value into the first (or any other) month's storage volume.

Section 5 MODEL RESULTS

The model was applied to find the yield associated with the three operational alternatives described in Section 3. Many model simulations were performed for each alternative. In these multiple runs, one of the limits in each of the alternatives was varied to find the optimum water yield. The alternatives and the parameter varied are shown in **Table 5-1**.

**Table 5-1
Model Simulations**

Alternative	Description	Varying Parameter
No. 1	Existing Firm Yield With Reserve	COH and SJRA diversions
No. 2	Maximum Firm Yield Without Reserve	Lake Houston call volume
No. 3	Maximum Average Yield With Reserve	Lake Houston call volume

The analysis shows that, in general, (a) lower minimum storage volumes result in more available water and (b) the yield results are not strongly influenced by the Lake Houston call volumes. The yield results are summarized in **Table 5.2** and explained in the following sections.

**Table 5.2
Summary of Model Results in Acre-Feet**

Alternative	Lake Conroe Min. Storage	Lake Houston Min. Storage	Lake Houston Call Volume	Firm Yield Acre (ft/month)	Average Yield
No. 1	140,940	46,900	113,610	22,070	22,070
No. 2	62,712	11,052	113,610 or less	27,000	27,000
No. 3	140,940	44,857	113,610 or less	0	26,600

ALTERNATIVE NO. 1

Alternative No. 1 is the current operational policy of the lakes, but it includes reserve storage volumes for use in an extended critical period. The reserve storage would also reduce the impacts on recreation, water quality, and the environment. The current operational policy calls for water from Lake Conroe when Lake Houston is drawn down two feet below the spillway crest, at 113,610 acre-feet of storage. The storage reserve was achieved by limiting the minimum storage of both lakes so that the surface area of the minimum pool is fifty percent of the surface area of the full pool. The Lake Houston water surface elevation that has fifty percent of the maximum surface area is 34.3 feet (46,900 acre-feet storage). The Lake Conroe 50 percent area elevation is 182 feet (140,940 acre-feet storage). This allows for a comparison of the current operation of the lakes with the other alternatives. The diversions to SJRA and COH were varied while the call volume was held constant. The results are as follows:

Section 5 MODEL RESULTS

Call volume	113,610 acre-feet (or lower)
Firm yield	22,070 acre-feet/month (15,940 to COH)
Average yield	Same as firm yield

ALTERNATIVE NO. 2

The objective of Alternative No. 2 was to find the maximum firm yield without holding any reserve storage for an extended critical period. The minimum pool levels were lowered to the physical minimum storage levels of the lakes. At these minimum pool levels more than the maximum amount of the combined water rights of COH (19,500 acre-feet) and SJRA (7,500 acre-feet) is obtainable.

The combined SJRA and COH diversions were set at the full water rights level of 27,000 acre-feet and the Lake Houston call volume was adjusted to examine the volume that would yield the 27,000 acre-feet of diversions. The minimum call volume to meet full yield is 28,820 acre-feet with a water surface elevation of about 30.6 feet, 13.9 feet below the crest of the spillway. If the Lake Houston call volume is set less than 28,820 acre-feet, the entire water right volume cannot be delivered each and every month. Any call volume higher than 28,820 acre-feet will yield the entire water right volume every month. The current policy call volume of 113,610 acre-feet will supply the full firm yield. The results are:

Call volume	28,820 acre-feet or higher (113,610 is okay)
Firm yield	27,000 acre-feet/month
Average yield	27,000 acre-feet/month

ALTERNATIVE NO. 3

The goal of Alternative No. 3 was to find the maximum average yield while having reserve storage. The Lake Houston deliveries were set to the full water right level of 27,000 acre-ft per month. The Lake Houston call volume was then adjusted, to determine whether higher average yields could be achieved. No attempt was made to deliver a firm supply in all months.

The average yield was found to be largely unaffected by changes in the Lake Houston call volume. An average yield of between 25,000 and 26,600 acre-ft per month was found for all call volumes above 40,000 acre-feet. The results are:

Call volume	113,610 acre-feet or lower (down to 40,000 acre-feet)
Firm yield	zero deliveries during certain months
Average yield	26,600 acre-feet/month

Section 6

RECOMMENDATIONS

ALTERNATIVES

An accurate planning model of the San Jacinto River System has been developed and used to evaluate three operational alternatives. However, because of the difficulty encountered in estimating the outflow of Lake Houston, the model should only be used for general planning of reservoir operations. Day-to-day, or month-to-month operations are not recommended with this model, without a more extensive hydrological analysis. This model will accurately display the overall effects of changing operational parameters, but the actual monthly volumes may not be completely reliable. Also future hydrological conditions may be more extreme than those observed in the past 45 years. With this in mind, the model provides support for the following recommendations:

1. Under the suggested minimum pool standards and full demand, the Lake Houston call volume could be lowered to 70,000 acre-feet. This assumes that there are not adverse Lake Houston water quality or recreational impacts associated with this operation. This volume is at a water surface elevation of 37.5 feet, seven feet below the spillway crest. This level will require the lowest volume of releases from Lake Conroe while maximizing the firm system yield.
2. If a greater firm yield is desired, the minimum reserve pool should be set at the maximum level that will still deliver the firm yield. The Lake Houston call volume may also have to be adjusted, to maintain appropriate releases from Lake Conroe.

SUGGESTIONS

There are many other factors that will affect the optimal operation of this reservoir system. The following suggestions were not investigated, but should be when data are available and resources permit.

1. Water from the Trinity River, a right recently obtained by SJRA, can be brought into the system through Luce Bayou. The "Luce Bayou Transbasin" column, set to zero acre-feet for all of the above alternatives, will introduce the water into the model. All of the model calculations that would be affected by this additional water supply already account for this flow in their respective formulas.
2. If desired, the effects of meeting an in-stream flow requirement between Lake Conroe and Lake Houston could be examined by adjusting the minimum parameter on the Lake Conroe Total Outflow field. It has been set at zero for the current analysis.
3. The model could be set up to calculate the percentage of months that a desired yield can be achieved. This information could help in the marketing of water to a customer that could tolerate an occasional delivery of a smaller amount of water than desired.
4. The model could be adjusted to include the yield of the City's other water sources. The diversions from Lake Houston could then be adjusted to evaluate the improvements in total

Section 6

RECOMMENDATIONS

City water supply which might be gained by conjunctively operating all of the City's water sources.

5. Additional detailed hydrological analysis should be performed to refine the reservoir inflows used in the model. Additional yield analysis, including stochastic generation of alternative time-series of inflows would also improve the reliability of the analysis of the City's water supply.
6. The model should be used to re-examine operation of the San Jacinto River System reservoirs as new or revised management goals are developed.

APPENDIX B

Calculation of Lake Houston Natural Inflow and GAIN

APPENDIX B

CALCULATION OF LAKE HOUSTON NATURAL INFLOW AND GAIN

Definitions of Appendix B spreadsheet columns. All amounts in acre-feet unless noted.

1. **Date** - Month of simulation
2. **Flow at H-10** - Historic volume of flow through gage
3. **H-10'** - Naturalized flow H-10
4. **Lake Houston Storage** - Storage data for Lake Houston
5. **Lake Houston TNRCC Diversions** - TNRCC diversion data for Lake Houston
6. **Lake Houston USGS Diversions** - USGS diversion data for Lake Houston
7. **Lake Houston Elev.** - Stage of Lake Houston, calculated using a storage-elevation lookup table
8. **Lake Houston Area** - Surface area of Lake Houston, calculated using an elevation-area lookup table (acres)
9. **Lake Houston Precip.** - Precipitation data for Lake Houston (inches)
10. **Lake Houston Evap.** - Evaporation data for Lake Houston (inches)
11. **Lake Houston Inflow** - $(4)_i - (4)_{i-1} + (6) + (8)x((10) - (9))/12$
12. **Lake Houston Daily Spill** - Monthly sum of daily spills calculated from daily lake storage
13. **Lake Houston Inflow Using Balance** - $(11) + (12)$
14. **F&N Correl Inflow** - $1.57x(15)$
15. **Sum of four Gages** - Sum of 4 reference gages, H-5, H-8, H-9, and H-16
16. **Natural Sum of four Gages** - $(15) - (2) + (3)$
17. **Natural LH Inflow Using F&N** - Maximum of $1.57x(16)$ or $(18) + 99$
18. **Natural Conroe Inflow** - C-4' from naturalization spreadsheet
19. **Final Lake Houston GAIN** - $(17) - (18)$

APPENDIX C

Evaluation of Alternatives Using San Jacinto River Reservoir Operations Model

C-1. Alternative No. 1

C-2. Alternative No. 2

C-3. Alternative No. 3

APPENDIX C RESERVOIR SIMULATION MODELS

Definitions of Appendix C spreadsheet columns. All amounts in acre-feet unless noted.

LAKE CONROE WATER BALANCE CALCULATIONS

1. **Month-Yr.** Month and year for the data in the row.
2. **Inflow C-4'.** The inflow to Lake Conroe as calculated in the hydrological analysis.
3. **Available Water.** The maximum amount of water in storage and stored during the month. Calculated as the minimum of the previous month's EOM storage plus the inflow,
$$(11)_{i-1} + (2), \text{ or the maximum storage shown at the top of the column.}$$
4. **Elev.** The stage of the lake corresponding to the average monthly storage volume
$$(((3) + (11)_{i-1})/2). \text{ Calculated by using an area-capacity lookup table.}$$
5. **Area.** The surface area, in acres, of the lake corresponding to the elevation in (4). Calculated by using an area-capacity lookup table.
6. **Precip.** The precipitation, in inches, at Lake Conroe.
7. **Lake Evap.** The lake evaporation, in inches, at Lake Conroe.
8. **Usable Water.** The available water discounting the meteorological effects. Calculated as the minimum of the Available Water plus the Precip. times the Area minus Evap. times the Area, or the maximum value shown at the top of the column.
9. **Diversions (Gulf St.).** The amount of water taken from Lake Conroe by Gulf States Utilities during the month.
10. **D.S. Calls.** The amount of water that is released from the lake because Lake Houston is low and needs the water. The Lake Houston storage volume that causes the outflow is set, and can be changed, as the top value at the top of the column, the outlet capacity amount is the bottom parameter.

The amount is calculated as:

If $(25) < \text{LH Storage Call Volume}$, then the minimum of 1/3 of the Available Storage, or the maximum of zero or the desired minus the Usable Water, or the Outlet Capacity.

Formula:

If $((25)_{i-1} < \text{Call}, \text{ then Min of } 0.33 \times (9)-\text{LCEOM}_{\min},$
 $\text{or } (23)+(24)+6000-(13)-(14)- (25)_{i-1} -\text{LHEOM}_{\min}, \text{ else zero.}$

(The 6,000 represents a maximum estimated Lake Houston evaporation loss.)

APPENDIX C **RESERVOIR SIMULATION MODELS**

- 11. EOM Storage.** The volume of water in Lake Conroe at the end of the month. Calculated as last month's EOM Storage plus the Total Inflow, minus DS Calls, minus the Diversions, plus the Precip times the Area, minus the Evap times the Area, limited by the capacity at the top of the spillway.

Formula:

$$(11)_{i-1} + (12) - (9) + (6)x(5)/12 - (7)x(5)/12 .$$

- 12. Lake Conroe Outflow.** The total volume of water that is flowing from Lake Conroe in the month (includes both releases and spills). Calculated as Last month's EOM Storage—EOM Storage (this month), plus Inflow C4', minus Diversions, plus Precip times Area, minus Evap times Area.

Formula:

$$(11)_{i-1} - (11) + (2) - (9) - (10) + (6)x(5)/12 - (7)x(5)/12 .$$

- 13. Lake Houston Gain.** The amount of water that the Lake Houston inflow gains, in addition to the outflow of Lake Conroe. Calculated in the hydrological analysis.

- 14. Luce Bayou Transbasin.** The amount of water brought into Lake Houston from the Trinity River, via Luce Bayou, for SJRA's use.

- 15. Total Inflow to Lake Houston.** The total amount of water that flows into Lake Houston. Calculated as the Lake Conroe Total Outflow plus the Lake Houston GAIN and Luce Bayou Transbasin, (12)+(13)+(14).

LAKE HOUSTON WATER BALANCE CALCULATIONS

- 16. Available Water.** The maximum amount of water in storage plus the water stored during the month. Calculated as the minimum of the previous month's EOM Storage plus the Total Inflow to Lake Houston, $(25)_{i-1} + (15)$, or the maximum limit, shown at the top of the column

- 17. Elev.** The stage of the lake corresponding to the average monthly storage volume, $[(17) + (25)_{i-1}] / 2$. Calculated by using an area-capacity lookup table.

- 18. Area.** The surface area, in acres, of the lake corresponding to the elevation in (18).

- 19. Precip.** The precipitation, in inches, at Lake Houston.

- 20. Lake Evap.** The lake evaporation, in inches, at Lake Houston.

- 21. Usable Water.** The Available Water discounting the meteorological effects. Calculated as the minimum of the Available Water plus the Precip. times the Area minus the Evap. times the Area, $((17) + (20)x(19) - (21)x(19))$, or the maximum limit shown at the top of the column.

APPENDIX C

RESERVOIR SIMULATION MODELS

22. **Diversion SJRA.** SJRA diversions as desired in the monthly amounts at top of column. If this is not available, it is calculated as 28% of the Usable Water minus the Lake Houston minimum storage, (22)-EOM_{min}.
23. **Diversion COH.** COH diversions as desired in the monthly amounts at top of column. If full amount not available, calculated as the Usable Water minus the SJRA diversions, minus the Lake Houston minimum storage, (22)-(23)-EOM_{min}.
24. **EOM Storage.** The volume of water in Lake Houston at the end of the month. Calculated as last month's EOM storage plus the total inflow, minus the diversions, plus the precip times the area, minus the evap times the area, limited by the capacity at the top of the spillway.

Formula:

$$(25)_{i-1} + (15) - (23) - (24) + (20)x(19)/12 - (21)x(19)/12$$

25. **Lake Houston Outflow.** The volume of water that flows over the Lake Houston spillway in the month. Calculated as Last month's EOM Storage—EOM Storage (this month), plus Total Inflow, minus diversions, plus precip times area, minus evap times area.

Formula:

$$(25)_{i-1} - (25) + (15) - (23) - (24) + (20)x(19)/12 - (21)x(19)/12.$$

APPENDIX C
RESERVOIR SIMULATION MODELS

Reservoir Simulation Models

C-2. Alternative No. 2

**Montgomery Watson
and Georgia A. Wilson & Assoc., Inc.**
LAKE HOUSTON / LAKE CONROE RESERVOIR OPERATION STUDY
San Jacinto River Reservoir Operations Model
Project # 3298.1023 / 14040
ALTERNATIVE #2: Maximum Firm Yield without Reserve Storage
Note: Column formulas are presented at start of Appendix C

WATER BALANCE FOR LAKE CONROE

(1) Month-Yr	(2) Inflow C4' (acre-ft)	(3) Maximum Storage (acre-ft)	(4) Water Surface Elev.	(5) Surface Area (acre)	(6) Precip. (in)	(7) Lake Evap. (in)	(8) Intermediate Water (acre-ft)	(9) Diversions (Gulf St) (acre-ft)

APPENDIX C
RESERVOIR SIMULATION MODELS

Reservoir Simulation Models

C-3. Alternative No. 3

**Montgomery Watson
and Georgia A. Wilson & Assoc., Inc.**
LAKE HOUSTON / LAKE CONROE RESERVOIR OPERATION STUDY
San Jacinto River Reservoir Operations Model
Project # 3298.1023 / 14040
ALTERNATIVE #3: Maximum Average Yield with Reserve Storage
Note: Column formulas are presented at start of Appendix C

WATER BALANCE FOR LAKE CONROE

(1) Month-Yr	(2) Inflow C4' (acre-ft)	(3) Available Water (acre-ft)	(4) Water Surface Elev.	(5) Surface Area (acre)	(6) Precip. (in)	(7) Lake Evap. (in)	(8) Usable Water (acre-ft)	(9) Diversions (Gulf St) (acre-ft)
